The use of a proper gasket is essential to tight closure of drums. The material from which the gaskets are made must

be chosen with regard to the material to be shipped, and also to the physical qualities, such as hardness, durability, and elasticity. Satisfactory gaskets may be made from numerous materials, such as hard fibre, leather, rubberised asbestos, etc. One of the principal causes of failures in gaskets is the fact that they are used too often. It would probably be a safe rule to require that no gasket should be used more than once.

Wooden Barrels.

The transportation of dangerous articles in wooden barrels and kegs will always result in accidents as long as those packages are authorised. This is especially true in connection with the lighter of the inflammable liquids and the more dangerous inflammable solids. The troubles lie principally in the inherent liability to slow leakage of barrels of the tight variety, and sifting of contents through cracks in slack barrels.

The shipment of alcohol in wooden barrels has resulted in comparatively large losses. In addition to the original weakness of the package these accidents are due to shippers using second-hand barrels without properly recoopering them, or barrels which do not actually come up to the standards prescribed. Faulty methods of loading may also contribute to the losses, since these packages are especially susceptible to damage through shock.

For new barrels the user is urged to require the manufacturer to certify to the fact that his product complies with the specifications, and to mark them to show such compliance. This responsibility placed upon the manufacturer of the package will secure some improvement.

For second-hand barrels only the most careful recoopering should be allowed, and care should also be taken that only those barrels actually complying with the specifications on original manufacture should be used for the dangerous articles.

The shipment of permanganate of potassium, the chlorates, and similar articles in slack barrels and kegs, is also giving some trouble. If these accidents continue, it will probably be necessary to limit these articles to metal containers. The present container, the slack barrel, is dangerous even after the contents are removed, and some fires have been caused by their use as second-hand packages for other articles.

Failures of shipping containers for inflammable liquids have often been due to overloading the container and the expansion due to rise in temperature. To determine the proper outage it is necessary to know the coefficient of expansion of the liquid and the maximum temperature range to which it may be subjected in transit or storage. Generally the more volatile and lighter liquids have the higher expansion coefficient.

Inflammable Solids.

The principal requirement for shipping containers of inflammable solids is the exclusion of air or moisture. Contact with air causes spontaneous oxidation with many of these substances, and often with sufficient degree to cause ignition. The degree of activity varies with these materials, and the attendant hazard of exposure to air is in proportion to this activity. Phosphorus, metallic sodium, fused sodium sulphide, and cobalt resinate are included in the class of inflammable solids.

The shipping containers for phosphorus commonly consist of sealed tin cans containing the phosphorus submerged in water; these cans are shipped in outside wooden boxes. This type of container has been satisfactory in direct shipment from factory to consumer. Where the material has been subjected to long storage before shipment, trouble has been caused by the slow rusting of the tin cans, allowing the escape of the water, the entrance of air, and in some cases the actual ignition of the phosphorus. It will be necessary to modify the specification of this container either by having a much heavier coating of tin on the tin can, or by requiring that the outer wooden box be provided with a hermetically sealed metallic lining. The latter will probably be the safer, as, no matter how secure the single inner package is, it is liable to be burst by the freezing of the water in cold weather.

Metallic sodium, while highly active, has caused very little trouble in shipments, owing to the fact that the shipping container is practically satisfactory. Large shipments are commonly made in the form of bricks or ingots, which are packed in heavy steel drums tightly closed. Smaller shipments are packed in hermetically sealed tin cans, packed in boxes, also immersed in oil in glass bottles surrounded by tin

* Abstract of paper read before the New York Section of the Society of Chemical Industry.

† U.S. Bureau of Explosives.

cans, the entire inner package being placed in a wooden box. Carload shipments are also made with the sodium cast solid in sheet-iron drums, such as are used for caustic soda. This package, while satisfactory for inter-plant shipments in solid carloads, is not permissible for general use.

Fused sodium sulphide is required to be shipped in tight iron drums, as when in wooden barrels it is liable to spontaneous heating and ignition, particularly in hot and damp weather. The crystallised sodium sulphide is more hazardous.

Oxidising Materials.

Materials classed as oxidising materials for transportation purposes include sodium peroxide, barium peroxide, potassium permanganate, potassium chlorate, and others of less activity and hazard. Sodium peroxide is inherently the most hazardous of these compounds, but owing to the effectiveness of the containers—tight steel drums or tight tins packed in wooden barrels or boxes—very little difficulty has been experienced in shipments. Barium peroxide formerly caused numerous fires, accompanied by heavy losses. At that time shipments were made in heavy and apparently tight wooden barrels. The barium peroxide was in the form of a fine but heavy powder. This powder in small quantities worked through the joints in the barrel, and it was found that friction of this powder between dry wooden surfaces readily produced fire. As a result of this investigation steel containers were required for shipments, and since this type of container has been used no fires have been reported in these shipments. The loss of the steamer *Volturno* by fire some six years ago is believed to have been caused by the ignition of barium peroxide shipped in wooden barrels.

Potassium permanganate and potassium chlorate are now shipped in wooden barrels or kegs. This practice is not entirely satisfactory, for there is a chance of fires being caused by friction if the contents escape from the package. Also, if the chlorate gets into a fire it occasionally causes quite severe explosions. An unexpected risk pertaining to wooden containers for chlorates has recently been noted. Fires have been caused by shipments of metal and hardware in second-hand chlorate kegs. The inner surface of these kegs was slightly crusted and impregnated with sodium chlorate. The friction of the metal pieces against the chlorate-impregnated surface started the fires. Immediate discovery and control of two fires disclosed definitely the cause. It is quite possible that other fires have been caused in this manner, and that the cause was never determined.

Corrosive Liquids.

The shipping containers used for corrosive liquids consist principally of tank cars, steel drums, glass carboys, and glass bottles. For sulphuric acid and mixing nitrating acid the tank car is very satisfactory, and the steel drum reasonably so. The glass carboy at its best is a fragile package. Sulphuric acid of 92 to 96 per cent. strength has but slight effect on iron or steel, but the stronger acid, oleum, has a much more marked effect. This effect is not uniform over the surface, but causes irregular pitting. This effect may be due to local impurities in the metal, but it is quite pronounced in the grade of steel used in making steel drums. Owing to the proposed development of air nitric acid plants, it is desired to ship strong nitric in tank cars with the minimum mixture of sulphuric acid which will serve to protect the steel from undue corrosion. So far as known, the least amount of sulphuric acid which has been successfully used for this purpose has been approximately 15 per cent. by weight of the total mixed acid. The corrosion of the steel depends not only on the amount of sulphuric acid, but also on the amount of water in the mixture. Investigations on this subject are still incomplete. The shipment of nitric acid has been the cause of heavy losses, not only of acid but also of equipment. These shipments must necessarily be made in glass carboys.

When the glass is not affected by the acid, frequent fires have occurred owing to the breakage of the carboys. The glass carboy of the usual capacity, about 12 gallons, is extremely fragile, and even with the best available packing there is considerable breakage due to the shocks caused by shifting and coupling of cars, or by train movement. The regulations require that no material, such as hay, straw, or similar combustible material, should be used as packing for nitric acid carboys. The packings most used are mineral wool and the so-called Stahl packing, which consists of four grooved, vertical wooden strips whose elasticity serves as the cushioning agent. While both of these packings are safer than hay for nitric acid carboys, nevertheless, numerous fires have occurred in shipments in both types of these carboys.

It is desirable that a carboy-box for nitric acid should have a metal or other liner that will hold the acid after the carboy

is broken, and not permit it to come in contact with the wooden boxes or the wooden floor and lining of the car. As yet, such a shipping container has not been developed to a commercial stage.

In the development of the carboy and its container it was necessary to determine accurately the resistance of the various combinations to severe stresses. In railroad transportation observation has shown that packages receive their greatest stresses in a direction parallel to the length of the car. These maximum stresses are due to coupling, switching, and sudden stops in train operation. The straight-sided carboy now in use is naturally more resistant to vertical stresses than to lateral ones, hence the freight car and the carboy make a combination in which the greatest stress comes on the weakest part of the carboy. As far as possible the packing serves to overcome this inherent weakness of the package.

Considerable difficulty has been caused at times by bursting of nitric acid carboys from internal pressure, due to expansion of the acid by heat or by decomposition of the acid by light. Experiments showed that with tightly closed bottles of nitric acid filled to 90 per cent. of capacity, and exposed to direct sunlight, a pressure of 17 lb. per sq. in. developed in three days. A considerably less pressure was produced by diffused daylight, and practically none in the absence of light. These tests showed the necessity of venting of nitric acid carboys, especially when ground-glass stoppers were used for chemically pure acid. Work is also being carried on in the development of porous stoppers for commercial acids which will permit the escape of vapours produced in transit.

Until recently, carboys were commonly closed by a loosely fitting earthen stopper held more or less securely in place by clay, plaster of Paris, and burlap. These stoppers were generally in fair condition when loaded in the car, but by the vibration and shocks of transportation they worked loose and in many cases jarred completely out of the necks of the carboys. This condition caused splashing of the acid from the carboys, which in some cases caused fire or injury to employees, and always caused rapid deterioration of the carboy boxes, the car floor, and lining.

Boxed carboys for the transportation of inflammable liquids and acids are a prolific source of trouble. Probably for nitric acid it will be necessary to adopt eventually a metal-lined box to retain the acid in case of accident. For ordinary acids, however, it is believed that careful attention to the following points will largely eliminate accidents due to the package: first, cushioning; second, closing device; third, repair.

Poor and insufficient cushioning cannot be cheap in the long run. It will cause accidents, and it will increase repair. The cushioning material should be 1½ in. to 2 in. in thickness all around the carboy, and should be carefully put in. A thin cushioning will give insufficient protection, and will quickly wear through by the constant rubbing of the carboy, while one full of lumps will cause the pressures to be brought on small areas of the carboy and cause breakage. A 1 in. thickness does not give space for proper packing or sufficient cushioning.

The use of elastic wooden strips for cushioning decreases initial costs, but has not proved successful from the standpoint of safety and final costs. Great care must be taken in manufacture and assembly, the elasticity of the wood is liable to be quickly destroyed by acid or acid fumes, and finally the repair and readjustment costs are certain to be high unless efficiency is neglected. I believe that some improvement will be obtained if packages cushioned with elastic wooden strips are used only where reshipments will not occur.

The closing device appears to be simply a question of cost. If a stopper is well made, an efficient gasket applied, and a strong metal fastening used, there will be no leakage. Already the improvements along this line have been great, but there is room for more.

The lack of proper repair of packing is probably one of the greatest causes for breakage of carboys. The carboy is fundamentally an improper package and unduly subject to breakage, and when the outside box and the cushioning deteriorate, the resulting package is exceedingly inefficient. Periodical and efficient repacking should be required.

Fires have been occasionally caused by the use of organic packing, such as sawdust, around bottles and jugs of bromine. This packing was improved later by saturation of the packing with the so-called bitter water, but still fires occurred at times, and it was finally required that bromine bottles or jugs should be packed in entirely incombustible packing.

Fires resulting in shipment of phosphorus trichloride necessitated the prohibition of any organic material as packing around the bottles or of any packing which will combine in any way with the phosphorus trichloride.

Compressed Gases.

The specifications for shipping containers for compressed or liquefied gases have been exceptionally successful in preventing losses and accidents. This is due to the fact that the pressure in cylinders of compressed or liquefied gases can be accurately determined and controlled. The cylinders can be made of a metal selected to have the proper chemical composition and the required tensile strength, elastic limit, and working qualities. Further, each cylinder, after being designed and made with a view to meeting these requirements, is subjected to a hydrostatic pressure test at a pressure sufficiently above any reasonable working pressure to ensure a proper factor of safety. It is required that when subjected to this pressure test the permanent expansion must not exceed 10 per cent. of the temporary expansion. A test of this nature assures that the actual bursting pressure will considerably exceed the test pressures, and at the same time the metal will not be overstrained, weakened, or hardened by the test. In the manufacture of compressed gas cylinders there is the advantage that the cylinders last for a long time, and hence the expense is distributed over a long series of shipments. Carbon dioxide cylinders have been in general use in the United States for a longer period than any other type of compressed gas cylinders. Many cylinders have been in use for more than 20 years. Many of the earlier cylinders were made according to specifications which would not at present be approved, yet there have been relatively few failures. Where cylinders of this type have failed it has generally been due not so much to excess pressure, but to brittleness of the metal. In most cases the bursting of the cylinders was caused by a shock such as is produced by a cylinder falling over or dropping from a car or wagon.

Acetylene cylinders have presented a peculiarly different problem in design and construction, because of the property of acetylene which causes it under certain conditions to dissociate with explosive violence when compressed to a pressure above two atmospheres. It can readily be liquefied, but in this condition is almost as dangerous as nitroglycerine. Experience has shown that the only safe way to store and ship compressed acetylene is in solution in acetone, which in turn is held in a porous filling mass in a steel cylinder. Asbestos blocks or other porous materials are used for this mass. This mass must have a porosity of not greater than 80 per cent., and must have no large voids in which an explosive reaction may start. The mass must be of sufficiently fine texture to be safe, and sufficiently rigid and durable to prevent sagging away from the walls of cylinder, even after long use and severe handling.

Aside from the tests of the cylinder by the usual hydrostatic tests, the filled and charged cylinders are tested as to liability to explosive dissociation of contents and bursting of the cylinders. The tests commonly applied are, first, placing charged cylinder in fire and observing whether gas escapes quietly by the safety vents or bursts cylinder; second, placing a charge of dynamite on cylinder sufficiently heavy to make deep dent in side wall, and yet not sufficient to break wall; third, burning a hole through wall of cylinder with a charge of thermit.

Shipping container specifications, as has been indicated, have been gradually developed to their present state. They are neither completed nor perfected; they do not always represent the best possible container, because they must be made within certain limiting costs to be available for commercial use. They represent the joint results of the experience of shippers of the commodities, manufacturers of the shipping containers, and of the carriers, plus thorough study of all the conditions. Additional specifications are being prepared from time to time as needed, and modifications and improvements are made in those previously drawn up. Further knowledge of the materials to be shipped, improvements in materials and manufacturing processes will suggest future developments and improvements in shipping containers.

AMERICA AND INDUSTRIAL ALCOHOL.—Despite prohibition the output of alcohol in the United States is expected to increase greatly, according to a bulletin issued by the American Chemical Society. The great development in industrial and engineering chemical activities which grew out of the war requires vast quantities of alcohol as a solvent. The millions of gallons that have been used for beverages will now be devoted to making this country independent of German chemical monopolies. A bill has been introduced in Congress called "The manufacture and sale of high-proof spirits for other than beverage purposes, and to insure an ample supply of alcohol and promote its use in scientific research and in the development of fuel, dye and other lawful industries."

IMPORTATION OF SHEEP DIPS INTO AUSTRALIA.

REASONS FOR PROHIBITION.

A DETAILED statement regarding the prohibition placed by the Commonwealth Government upon the importation of sheep dips was furnished to the Australian House of Representatives recently by the Minister of Customs, in reply to a series of questions.

The Minister said that towards the end of 1917, owing to the lack of shipping facilities, the position with regard to the supply of sheep dip was becoming acute, and the wool-producing interests, which were dependent on supplies of dip from overseas, were threatened with serious loss. All the raw materials used in the manufacture of dips were also urgently required for munition purposes by the British Government, and it was not considered desirable to continue drawing upon Great Britain for these essential supplies used in the prosecution of the war, if other arrangements could be made. As the position was becoming daily more acute, negotiations were commenced on behalf of the Commonwealth by Sir John Higgins, in the hope that one of the largest British sheep dip manufacturers would establish a factory in the Commonwealth. Various proposals were made to Messrs. Cooper and Nephews, with a view to inducing them to manufacture their dips in Australia, but the company sought special conditions regarding plant and machinery, labour, etc., which could not be granted to any applicant. Negotiations were then opened up with the Victor Leggo company—one of the largest arsenic producers in Australia—to undertake the manufacture of arsenical sheep and cattle dips. That company immediately agreed to accept the responsibility of erecting works, and expended several thousands of pounds in plant and equipment. He understood that this firm entered into negotiations with other manufacturers which enabled them jointly to guarantee the necessary quantity of dips for Australian requirements. Any firms who were prepared to manufacture dips were promised by Mr. Hughes support against overseas manufacturers. When it became apparent that the requirements of Australia could be fully met by local manufacturers, a cable was sent to the Ministry of Munitions in England, which controlled the issue of raw materials to manufacturers and the priority of shipping space, in the following terms:—

Sheep Dip. Commonwealth Central Wool Committee, after careful consideration, advise unnecessary obtain sheep dips Great Britain, as requirements can be effectively met by local manufacturers.

The British Munitions department subsequently inquired through the High Commissioner whether Australia actually needed any sheep dip from the United Kingdom. A reply was sent through the same channel, in which it was stated—"Please give definite assurance Ministry Munitions importations unnecessary." Notwithstanding that the central wool committee advised the Government that the imported sheep dip was not required, and the Commonwealth Government advised the British Government accordingly, and notwithstanding, also, that the Commonwealth Government was constantly pressing the British Government for space for urgently, and in some cases desperately, needed goods, a portion of the shipping space still continued to be occupied by sheep dip, and not by things the Government pressed and asked for. There was therefore no option but to impose an embargo on the importation of dips.

Sheep and cattle dips, added the Minister, might be classified under two main divisions—arsenical and carbolic or phenol. Australia produced arsenic as a by-product in the treatment of auriferous arsenical ores, and in quantities not only sufficient for all Commonwealth requirements, but also for exportation. Shipments of Australian white arsenic had been made to sheep dip manufacturers in Great Britain. During the war many parcels of arsenical compound had been shipped to Great Britain. From coal tar, millions of gallons of which were produced annually at gasworks in Australia, ample raw material was available for the production of all phenol dips. There were now two Australian manufacturers of powder and phenol dips respectively, operating on a large scale. There were also other companies operating on a smaller scale. An exhaustive analytical and physical examination had been made of the several imported Australian dips—powder, paste and liquid—on the market, with the result that the Australian article had been found to differ in no material respect from the imported dip, and, value for value, to be a cheaper article.

ACID PRODUCTION IN THE UNITED STATES.

THE production of sulphuric acid in the United States increased gradually from 1913 to 1918, as is shown in the following table:—

	Calculated as 100 per cent. acid.
	Short tons.
1913.....	2,250,000
1914.....	2,365,000
1915.....	2,610,000
1916.....	3,930,000
1917.....	4,460,000
1918.....	4,705,000

Germany produced 1,495,000 tons of sulphuric acid in 1912, and Italy 571,000 tons in 1914. Great Britain produced 1,348,000 tons of monohydrate (100 per cent. sulphuric acid) in 1917.

The consumption of sulphuric acid in industry in the United States, as estimated in the summer of 1918, was as follows: (1) Explosives (directly or indirectly), including phenol and nitric acid, 35 per cent.; (2) fertilisers, 27.8 per cent.; (3) oil refineries, 11.2 per cent.; (4) chemicals and drugs, including hydrochloric acid, nitric acid for purposes other than explosives, and ammonium sulphate, 9.6 per cent.; (5) steel pickling and galvanising, 9.1 per cent.; (6) miscellaneous, 7.3 per cent. The estimated quantity of this acid used in 1918 in the manufacture of military explosives was 1,646,000 tons (calculated as 100 per cent. acid).

On January 1, 1918, it was estimated that 28.8 per cent. of the country's production of sulphuric acid was being made by the contact process, and 71.2 per cent. by the chamber process. Similarly, of the estimated production of 66° Bé. acid on the same date, 41.6 per cent. was made by concentration from the weaker chamber acid and 58.4 per cent. directly by the contact process. The country was producing sulphuric acid in the fall of 1918 to only 89 per cent. of its rated production capacity. Difficulties in the fuel and labour supply, as well as in domestic transportation of raw commodities, hindered production. Of the entire sulphuric acid production capacity of the United States on November 1, 1918, 10.8 per cent. was at Government plants, 11.7 per cent. at plants making explosives, and 77.5 per cent. at all other plants.

The quantity of 50° Bé. sulphuric acid produced from the various sulphur material for 1918 as estimated in the summer of 1918 is shown in the following table:—

Source of sulphur.	Tons of 50° Bé. Acid Produced.
Sulphur	4,270,000
Domestic pyrites	1,150,000
Zinc ore fumes	900,000
Copper ore fumes	800,000
Spanish pyrites	600,000
Canadian pyrites	480,000
Total	8,200,000

The tonnage of 42° Bé. nitric acid produced increased from 54,000 in 1904 to 78,000 in 1914, to 602,000 in 1917, and to 945,000 in 1918. The production in 1917 was, however, only 74 per cent. of the rated capacity as estimated by the producers. Of the large tonnage produced in 1917, 55.5 per cent. was used in the manufacture of military explosives.

Hydrochloric acid production statistics are available only for 1914 and 1918. The tonnage, calculated as 20° Bé. acid, increased from 168,000 in 1914 to 223,000 in 1918. The increase in the production of hydrochloric acid since 1899 has been relatively uniform as compared with that of sulphuric and nitric acids.

The production of domestic pyrites increased only 35 per cent. from 1913 to 1918, or, expressed in long tons, from 341,338 to 460,000 (estimated). On the other hand, the production of domestic brimstone in 1918 was 470 per cent. of the 1913 production. There are several reasons for this extreme divergence. The sulphuric acid manufacturers were adjusted very largely to the use of pyrites, but required only slightly different conditions for burning brimstone. Inasmuch as considerable time is necessary to develop a pyrites mine, while enormous deposits of practically pure brimstone were available with comparatively small additions or development, the latter were given the greater attention.

Every effort was made to utilise to the best advantage the sulphur fumes obtained in the roasting of copper and zinc ores. The production of sulphuric acid from this source averaged 24.4 per cent. of the total production during the period 1911-1916, and remained remarkably constant. However, the new apparatus required for the recovery of the sulphur dioxide from the waste gases at the small plants

roasting zinc ores was expensive. In general, these plants could be arranged to make this conservation in spite of larger costs.

SULPHATE OF AMMONIA.

HIGHER PRICES FOR FUTURE DELIVERY.

THE Board of Agriculture and Fisheries have come to an agreement with the makers of sulphate of ammonia with regard to the maximum prices to be charged for this fertiliser for home agricultural use, for delivery in the eight months October, 1919, to May, 1920. These prices are appreciably higher than those ruling during last season, owing to the fact that the Government subsidy given to makers during the war has now been withdrawn. The agreed maximum prices are fixed on a commercial basis which has to cover the substantial increases which have occurred since last year in the cost of coal, wages, and raw materials. The Board consider that these prices are not more than are necessary to secure to the manufacturers a reasonable trade profit.

The agreed maximum prices for sale in lots of not less than two tons for delivery by rail or water to purchaser's nearest railway station or wharf in Great Britain, less a trade discount to agricultural merchants, dealers, and co-operative societies, are as follows:—

Month of Delivery.	Price per ton in bags, net cash.
	£ s. d.
October, 1919	20 10 0
November	20 15 0
December	21 0 0
January, 1920	21 7 6
February	21 15 0
March, April, and May	22 0 0

The above prices are for 24½ per cent. ammonia, and will be increased by 4s. per ton for each complete .25 per cent. ammonia over 24½ per cent, and by a further 5s. per ton if sellers guarantee the free acid not to exceed .25 per cent.; and should be reduced by 4s. per ton if the content of ammonia is less than 24½ per cent. but not less than 24½ per cent.; by 8s. per ton if the content of ammonia is less than 24½ per cent. but not less than 24 per cent.; and so on. The quantitative increases and reductions apply only to deliveries of 20wts. and over. If the sulphate is specially ground or pulverised at buyer's request, an additional charge not exceeding 5s. per ton may be made.

The above prices are delivered free in two-ton lots and upwards to buyer's or consumer's nearest railway station or wharf in Great Britain (or f.o.b. British port when the ultimate destination is Ireland, Isle of Man, or Channel Islands); or ex works free to road vehicle to be supplied by the buyer; and packed in single bags containing about 20wts. net to be supplied free by sellers, tare allowed. The seller is not bound to make any allowance if the buyer elects to take delivery by road vehicle ex works. When credit is given, a reasonable extra charge may be made, but the discount allowed for prompt payment should be quoted on the invoice.

For deliveries of less than two tons the following extra charges may be made:—

1 ton and over, but less than 2 tons, 10/- per ton over 2-ton price.
2 cwt. and over, but less than 1 ton, 1/- per cwt. over 2-ton price.
1 cwt. and over, but less than 2 cwt., 2/- per cwt. over 2-ton price.
28 lb. and over, but less than 1 cwt., 3/- per cwt. over 2-ton price.
14 lb. and over, but less than 28 lb., 4/- per cwt. over 2-ton price.

A commission of 10s. per ton will be allowed to fertiliser mixers, agricultural merchants, and co-operative societies on all deliveries of two tons and over. Orders should be sent to the Sulphate of Ammonia Association, 84, Horseferry Road, S W. 1.

LICENCES UNDER GERMAN DYE PATENTS.—British Dyes, Ltd., have been granted licences to work 49 patents, ranging from the year 1904 to 1914, in the name of Farbenfabriken vorm. Friedrich Bayer and Co. Messrs. L. B. Holliday and Co. have also been granted licences to work two patents—one in the name of L. Haas, and the other in the name of Leopold Cassella and Co.

SCIENTIFIC AND INDUSTRIAL RESEARCH.

PRIVY COUNCIL COMMITTEE'S ANNUAL REPORT.

THE fourth annual report of the Committee of the Privy Council for Scientific and Industrial Research for the year ending July 31, 1919, has just been issued. The Advisory Council's report (Sir William S. McCormick, LL.D., administrative chairman) is divided into three parts. Part I. describes the progress made in the establishing of research associations; Part II. deals with the growing organisation of research for national purposes; and Part III. describes the more important developments that have taken place in the conduct of researches initiated by other bodies and aided by grants from the Department.

Industrial Research Organisations.

At the time of the issue of the last annual report, some thirty industries were actively engaged in preliminary work for the establishment of research associations. Licences had been issued to the British Photographic Research Association, the British Scientific Instrument Research Association, and the British Research Association for the Woollen and Worsted Industries; the memoranda and articles of the British Cotton Industry Research Association, the British Portland Cement Research Association, the Research Association of British Rubber and Tyre Manufacturers, and the British Motor and Allied Manufacturers, were approaching completion. Six other industries were engaged in drafting articles, and the remainder were considering the necessary preliminary negotiations.

During the past year steady progress has been made with the formation and development of research associations. The British Photographic Research Association has completed its preliminary survey of the field of research, and has drafted a valuable and comprehensive scheme of work, which other research associations might usefully consult as an example of the way in which their plans of campaign may be attractively presented to their members. The Research Association has decided to attack the problems which confront it not only by the empirical methods which have brought the photographic industry the success it has already achieved, but also by investigating fundamental principles. This is a long-sighted view which is welcome. A number of investigations of direct industrial application have already been completed. For instance, useful experiments have been conducted on gelatine and on photographic emulsions, and a successful process, which it is intended to patent, has been discovered by which it is possible to stain wood black or grey right through. This process is expected to be quite economical and suitable for use on a large scale; and it is interesting to note that the research was guided by a knowledge of the methods used in dyeing cotton. The Association also makes a point of publishing all results of research which are likely to be of general interest and not of immediate use for application to specific problems of the industry.

The British Scientific Instrument Research Association, which was planned at the outset "on lines broad enough to include all scientific instrument makers," began by being mainly an association of makers of optical instruments, although it included several important firms outside the optical instrument industry. During the year the prospect, foreshadowed in the last report, of its becoming the representative industrial body dealing with the application of science to the manufacture of instruments of precision, has been closely approached, for the bulk of the important firms in the X-ray electro-medical instrument industry and the electrical scientific instrument industry joined it. It has, therefore, been necessary to extend the scale of grants to this Association. Under the original agreement the Department guaranteed a total expenditure by the Association of not more than £40,000. during the first five years on a scheme of research approved annually by the Advisory Council, on condition that the members of the Association made an immediate contribution of £4,000. out of the net revenue account. Under the extended agreement the Department has guaranteed an additional expenditure of £24,000. to £30,000. on condition that the newly admitted members make an immediate contribution of £2,400. to £3,000. out of their net revenue account. These very exceptional terms have been given to the British Scientific Instrument Research Association because their industry falls wholly within the class of "key" industries. Another industry falling partly into this class is glass manufacture. The making of scientific glassware in this country is essential to the national interests, and can only be

developed in connection with the manufacture of other kinds of glass. Accordingly, an arrangement has been made with the Glass Research Association that the Department will guarantee an expenditure of £20,000. a year for five years on condition that the members of the Association raise £5,000. a year during the same period.

"Key" Industries.

The reference in last year's report to the special Government encouragement recommended for certain "key" industries by the Committee on Commercial and Industrial Policy after the War appears to have given rise to some misunderstanding. It has been suggested to the Department that it should make grants at a higher rate than pound for pound to certain industries, because other industries are dependent upon them for their welfare or existence, and that these industries should therefore be regarded as "key" or "pivotal."

In an old industrial country such as this, where trade has been joined to trade and industry to industry for generations, the resulting structure has become so complex that there are few industries on which others are not dependent to a greater or less degree. Thus, no industry using power can be carried on without the help of the coal industry or the engineering industry, while most industries depend more or less upon the building trade, the chemical industry, the leather industry, or one or other of the textile industries. In a sense, therefore, a large proportion of our trades can be regarded as "pivotal."

If claims for exceptional treatment by the Department are to be justified, the definition of a "pivotal" industry must be narrowed. This can readily be done by considering the purpose for which the Department's funds are intended. Their sole aim is the stimulation and prosecution of research, and accordingly they can only be made at a high rate to industries for which the cost of the necessary research is great in relation to their means.

Further, they can only be given on a scale higher than the normal when it can be shown that the industry concerned is essential to the existence of larger industries and to the defence of the realm. If the Government were on these grounds to accord preferential treatment to a particular industry or group of industries by special adjustments of their general commercial policy, this action would in itself justify the Department in refusing to make abnormal grants to any others. But even in these cases the Department would not be justified in making abnormal grants without further inquiry, since it would be necessary to have proof that the special commercial advantages to individual firms which the Government policy might be expected to afford did not in themselves constitute adequate assistance from the State. This proof, so far as the Department is concerned, would only be complete if it showed that the cost of the research required for the maintenance and development of the industry in question is so large a factor in the necessary costs of production that the ordinary grants of the Department would be insufficient.

New Research Associations.

A number of industries depending for their raw materials on supplies imported from tropical countries have taken active steps to ensure that the problems arising in their processes shall receive scientific investigation, and accordingly the British Empire Sugar Research Association has been established, and the Research Association of British Rubber and Tyre Manufacturers will shortly come into existence.

Reference was made in last year's report to the difficulties encountered in securing joint action between the makers and users of refractories in the task of organising research on these important materials, and it was suggested that the most accessible line of advance would be found in the makers organising themselves, and then encouraging the users to come in as and when they felt inclined to do so. It is therefore of great interest to be able to record the fact that a separate research association for the makers of refractories is just about to be launched, and that its promoters have secured the support of a number of users of these materials. The users of refractories have also been active, and in addition to the Glass Research Association, to which reference has already been made, a Portland Cement Research Association is now at work, while the scheme drawn up by the representatives of the Non-ferrous Metals Research Association has been approved by the Department, and its memorandum and articles of association are under consideration by the Board of Trade.

The task of providing munitions of war, and the difficulties of placing industry once more on a peace basis, have necessarily absorbed much of the time and energies of the leaders

of industry, and consequently the fact that research associations have been approved at the rate of about one a month during the year may be regarded as very satisfactory, since it indicates a real intention on the part of manufacturers to see that workshop and mill practice is based on sound scientific principles. Doubts as to the future organisation of the industry have, however, for the present, completely put an end to the movement of the Mining Association of Great Britain, mentioned in the last report, towards the establishment of a single research association for the whole kingdom. The increased cost of labour has caused the outlook for the shale-oil industry to be so anxious that the establishment of the Research Association, which had been approved, has been suspended, although the firms had already paid in their subscriptions.

Improved Conditions of Grant.

In January of this year revised conditions of grant were issued making it quite clear that all results of investigation obtained by research associations belong to the associations themselves, which hold them in trust for the benefit of their members. The ownership is, however, subject to two conditions.

The Department, acting in the national interest, may (a) after consultation with the Council of the Association, secure that the results of investigations shall be communicated to other industries on such terms of payment and such other conditions as the Department, after consultation with the Council of the Association concerned and with other co-operating bodies and persons, deem fair and reasonable; (b) prohibit the communication of any results to any foreign person or body or to any person or body under foreign control.

This modification has been welcomed by manufacturers because it fulfils more completely the intention of the Government to entrust to them as full powers in connection with research for their industry as are compatible with State assistance.

Workers Under Research Associations.

The conditions of employment offered by the associations to their scientific workers, whether directly engaged or attached to a university or college, will need very careful study. The war has made the scientific man realise his vital importance to the community as a means of defence, and a certain class-consciousness has arisen among the younger men, of which account must be taken. The need of the community may be, and we believe is, no less urgent in time of peace. But it is not so insistent, because the processes of peace, owing to their relative complexity, are so much slower, and this fact also must be brought into reckoning. Yet discussion of the terms of employment offered by firms, and of the status and remuneration of scientific and technical workers under Government, can only do good, and the proposals or criticisms which have recently appeared will no doubt be carefully considered by the research associations. It has been claimed by some that research workers employed by a firm or a research association should have the right to patent and exploit for their own benefit any discoveries they may make which their employers may be unwilling to take up. This claim has, at first sight, the appearance of justice, but, on the other hand, it has been well pointed out that the work done in the research laboratories of firms and research associations is essentially team-work in which the contribution of each member is part of a whole, and that no arrangement which encourages individuals to play for their own hands is consistent with the well-being either of their colleagues or of their employers. The true solution is to be found in the adoption of an enlightened and generous policy by the association or firm.

Closely connected with this matter is the attitude of research associations to the consultant and analyst. The position of the consultant or analyst is one of great importance to the industrial community. The work of this profession ranges from analysis or testing of a more or less routine kind to research of a high order. Many firms, and even whole industries, have relied entirely in the past upon the professional consultant for such research as they have wished to undertake.

It would not be surprising if some members of a profession which has won for itself a reputation for high accuracy and skilful technique, and which includes among its leaders original workers of the highest order, should view with doubt the possible inclusion of powerful trade associations into their own field of work. It is accordingly very important that research associations should define clearly, and from the beginning, their attitude in this important matter. It will be

impossible for even the most powerful and wealthy associations to cover the whole field of investigation opened up by the needs of their industry, and the independent specialist is at least as likely to be called to their aid as the worker in college or university. Moreover, individual firms which are progressive will often need to have problems worked out for their own purposes, some of them doubtless suggested by the work of the association to which they belong. These problems are as likely to be entrusted to their independent consultant as to the association itself, and particularly so if the independent worker has specialised in that direction. The real danger lies, and will continue to lie for many years ahead, in the serious shortage of competent research workers in every field of activity.

Research into Accessories.

Again, the continued progress of knowledge leads inevitably to the development of subjects having two or more sciences as their foundation, and consequently of interest to each of them. Similarly the advance of industry and the development of systematic research in relation to it will lead, and indeed has already led, to the recognition of problems which, though they are not perhaps of vital importance to any one industry, are yet of great interest to several. How is research into topics of this kind to be organised? The memoranda and articles of association approved by the Department provide for co-operation between two or more associations in objects of interest common to each, but the method of co-operation has still to be devised. The study of adhesives is an example of the kind of problem we have in mind. It is possible that in due course a new industry may emerge, the object of which will be to produce in a systematic way all the many types of adhesive that are needed. Such an industry would necessarily be of a highly scientific kind, and at present it does not exist in any organised form. Meantime how should those industries which use adhesives, or which produce the raw or intermediate materials from which adhesives could be made, approach this urgent problem? It is possible that the establishment of a joint committee financed by the several associations interested in the question might be a suitable device.

Proposed Records Bureau.

The most important of the questions before the recent conference of research associations was undoubtedly that of a Records Bureau. Proposals have been made from time to time to the Department from many sources that it should establish a national clearing-house for the results of research, or even, in the opinion of the more optimistic, for technical information of all kinds. The Advisory Council have carefully considered these proposals as they have arisen, but they have decided to take no action with regard to them. What is needed in this country is not so much additional machinery for collecting the raw material of knowledge, as more adequate means for the systematic review of existing collections of information, and its presentation by properly trained workers in a form which will place the important and the less important in perspective for the benefit of those who need to apply it in practice.

It seems certain none the less that the Department can, under suitable conditions and within carefully defined limits, play an important part as a bureau of information relating to research. The research associations expect to gain through the Department much knowledge of the work of other research organisations. This appears to the Advisory Council to be a reasonable expectation, and it is from this point that their proposals start. What limits should be set to them? In the first place, the Department must only undertake work which it can do efficiently. Further, its information must be thoroughly reliable. These two conditions suggest that the Department should be officially responsible for receiving, abstracting, filing, and collating only formal written communications from research workers, boards, institutions, or associations related to or supervised by the Department. This information will be regarded as confidential and will not be communicated, except in writing, and after consultation with the research worker or organisation from which it has been received. Although the Records Bureau will not attempt to make a comprehensive collection of information relating to the results of research, it is certain that a good deal of miscellaneous information of this kind will come into the possession of the Department, and the Bureau will not exclude the collection, filing, and communication of non-confidential information of evident or probable value. Any information received from other Government Departments as to the results of research conducted by or for them will similarly be communicated—if confidential in nature—under the rules above

described. Even with these limitations, however, it is obvious that the work of the Bureau will be a large undertaking. Research for the Department is now, or will be, carried out under the following headings:—

- (a) Research institutions, such as the National Physical Laboratory and the Fuel Research Station.
- (b) Research conducted by other research boards or committees of the Department.
- (c) Research associations.
- (d) Researches by scientific and professional bodies aided by the Department.
- (e) Researches by individuals aided by grants from the Department.

When to the results of the work of these organisations and individuals are added the bulky compilations dealing with the researches of other Departments of State the mass of material may necessitate a considerable subdivision of the work of the Bureau. But the safe course will be to begin on a small scale, and to develop gradually in the light of the experience gained during the initial stages. It is suggested that the Bureau may also prove useful in two ancillary directions. It occasionally happens that lists of materials and apparatus which might be of use for research are received from dealers in this country and abroad. It will be unnecessary to record all these lists, but specific items in them may be of interest and importance, to one or other of the organisations connected with the Department, and such information will from time to time be circulated. Further, since the waste product of one industry is often the raw material of another, it is possible that a research association may draw attention to a by-product of which the industry it represents finds it difficult to dispose. The Bureau will record the existence of such by-products and notify them to other research associations with a view to their being tested and utilised.

The National Physical Laboratory.

The cessation of hostilities has naturally caused a large reduction in the amount of work done by the Laboratory for the War Departments, but other Government work has grown. In the physics department an interesting measuring instrument and a steady source of current have been devised for the calibration of frequency meters, and an improved method of comparing tuning forks of low frequency has been successfully used. Work on the specific heats and thermal conductivities of lubricating oils have been investigated in connection with the research into these oils undertaken in the engineering department at the request of the Advisory Council's Lubricants and Lubrication Inquiry Committee. Interesting tests have also been made to determine the heat necessary to raise the temperature of certain vegetable oils intended for varnish-making from that of the room to 350° C. A beginning has been made with the testing of chemical glassware of the highest grade (Class A), and it is hoped that the regulations for testing Class B ware will soon be settled.

Great progress has been made in the metallurgy department with the study of the constitution of the groups of ternary alloys which are likely to prove important for practical purposes, and the possibilities of some of them "which have very remarkable properties have now been placed on a secure foundation." The causes of failure in boiler plates have been further studied, and the results communicated to the Iron and Steel Institute, while much work has been done on the case-hardening and heat treatment of alloy steels. The research on magnet steels has made good progress, and, with a view to placing the study of tungsten steels on a better basis, an investigation has begun into the constitution of the alloys of iron and tungsten. The work on the production of crucibles resistant to the attack of molten glass has also been continued.

The Fuel Research Board.

In their last report the Advisory Council stated that the actual erection of the Research Station at East Greenwich had been taken over by H.M. Office of Works. It was then anticipated that some of the buildings would be ready for occupation in the autumn of 1918. Owing, however, to shortage of labour and materials, as well as to serious difficulties with the foundations, the main buildings are only now nearing completion. The laboratories and offices have been partly in use, and some members of the permanent staff have been regularly at the station since February. The Lord President, on the advice of the Director of Fuel Research, has appointed Engineer Commander Fraser Shaw, R.N., to be engineer-in-chief of the station.

In view of the cessation of war conditions and of the recent developments in the coal-mining industry, the Fuel Research

Board feel it to be desirable that they should reconsider the whole outlook as regards their researches into the more economical use of the fuel resources of the nation. In a report which they propose to issue shortly they intend to deal with this subject.

The Fuel Research Board, having given most careful attention to both the principal and the supplementary reports of the Irish Peat Inquiry Committee, have submitted their views to the Committee of Council. The matter is still under the consideration of the Government.

Professor Pierce F. Purcell, Assoc. M.Inst.C.E., who rendered valuable service as secretary of the Irish Peat Inquiry Committee, also placed his experience and expert knowledge at the disposal of the Coal Controller in his efforts to augment fuel supplies by encouraging the winning and use of peat in England. Professor Purcell inspected and reported upon many of the bogs in this country. He also prepared a leaflet descriptive of the most satisfactory methods of winning peat by hand, which was issued by the Coal Controller.

Power Alcohol.

In October last Mr. Walter Long appointed an inter-departmental Committee to consider and report upon—

- (1) The various available sources of supply of alcohol, the methods of manufacture, and the cost of the product.
- (2) The suitability of alcohol, either alone or in admixture with solid, liquid, or gaseous combustible substances, for use in internal-combustion engines and the modifications necessary to the attainment of efficiency.
- (3) The question of denaturing the alcohol, and the alterations to be made in the present Excise arrangements.

Mr. Long invited the Department to nominate a representative to sit on the committee, and, upon the advice of the Director of Fuel Research, and having regard to the general questions of policy raised, the Committee of Council selected the secretary of the Department to serve. The committee presented an interesting report on June 23 last, in which the wide range of possible sources for "power alcohol" was reviewed, the directions in which further inquiry and investigation are desirable were indicated, and improvements in present arrangements for denaturing, importation, and distribution were suggested. The Government will no doubt give careful consideration to the recommendations of the committee. Meantime the Advisory Council desire to associate themselves with their view that should any permanent organisation be established as the committee desire, it is of great importance that the arrangements made should be such as to bring the study of alcohol as a fuel into close association with that of other forms of fuel, whether solid, liquid, or gaseous, for the economic factor will in the end inevitably condition the possibilities of its extended application. The price, in other words, will be found to be the decisive element in its use.

The Food Investigation Board.

The Oils and Fats Committee of the Food Investigation Board was appointed to investigate certain problems submitted to the Department by the Ministry of Food. The refining of fine edible oils is practically a new industry in this country, and a Chemical Sub-committee has been at work on the many problems that are involved. The question of discovering substitutes for edible oils used in industry was one of considerable importance during the war, and was entrusted to a special sub-committee, but more recently other problems referred by the Ministry of Food have gained in relative urgency. In particular, the distribution of accessory food-stuffs in edible fats of various origin and history is a matter of vital effect upon the health of the masses of the people, and especially of the very young. With the assistance of the Medical Research Committee this important question is now engaging active attention.

The Tin and Tungsten Research Board.

The Tin and Tungsten Research Board, which was established last year, has now issued its first annual report. The contributions from local mineowners and landlords amounted to £2,753 16s., and the expenditure on research and incidental expenses to £2,512 14s. 7d., half of which has been met by the Committee of Council, leaving a balance in hand (including interest from invested funds and from the sum transferred by the Institution of Mining and Metallurgy) of £2,001 16s. 6d., which will be carried forward to next year's account. The work of the Board has been hampered by the shortage of materials and research workers, but six papers have been read before the Institution of Mining and Metallurgy, in which the results of some of the investigations have

been described; while Professor Truscott, assisted by Messrs. J. H. Goodchild, K. S. Low, and H. L. Burnie, has completed his research into slime treatment on Cornish frames, and his conclusions have been published in Bulletin No. 175 of the Institution. As a result of the whole series of tests, modifications of two fundamental factors in policy have suggested themselves, one being in favour of rapid enrichment, in place of the present practice of gradual enrichment, the other being in favour of extending the practice of fine grinding the sand residues. Professor Truscott claims that by a systematic adoption of these two practices an increase of 11 per cent. of the present recovery of tin would be gained. A number of other investigations carried out for the Board are described in the notes by Sir Thomas Kirke Rose, the chairman of the Research Committee, which are appended to the Board's report. It is anticipated that more rapid progress will be possible during the current year, as arrangements have been made to attack systematically the chemico-physical problems which underlie the extraction of metals from their ores with special regard to the recovery of tin and tungsten.

The governing bodies of the Imperial College of Science and Technology and of the School of Metalliferous Mining (Cornwall) have continued to afford laboratory facilities, and various Cornish mineowners have supplied ores free of charge, and made arrangements for carrying out tests on their dressing floors. We desire to tender our thanks to them and to those investigators who have gratuitously given their services to the work.

(To be continued.)

IMPORT RESTRICTIONS AND HIGH PRICES OF CHEMICALS.

At a recent meeting of the Advisory Committee on Drugs, Chemicals, and Dyestuffs of the American Chamber of Commerce in London—Mr. Irving A. Keene (chairman) presiding,—it was stated that import licences were being refused for all coal-tar derivatives, and also for phenacetin, aspirin, and acentanilid, the reason being given that the quantity manufactured in this country was sufficient to supply the demand. The committee were agreed that because the demand was so much greater than the supply, which was limited owing to the fact that none was coming into the country, the prices were prohibitive. Some members, however, were of the opinion that the Government were fully alive to this fact, and were watching the situation closely. As soon as they had satisfied themselves that any supplies were being held up in order to sell when the price should rise, the Government would allow freer imports to bring down the price. It was decided that it would be well to point out to the Board of Trade that the prices had been forced up by the import prohibition.

Mr. R. Frothingham suggested that the price argument might not produce results in regard to phenacetin if it were really impossible at present for British manufacturers to manufacture it here at a lower price. The Board of Trade would probably be inclined to protect this industry in so far as seemed called for. The best argument with the Board of Trade would seem to be a presentation of the consumers' part.

The following resolution was drafted and proposed by Mr. A. Withy, seconded by Dr. J. Bebie, and carried: "While it is understood that the British Government are fully justified in protecting home industries to the greatest extent, we venture to suggest that consumers should also be considered; and inasmuch as salicylates, phenacetin, vanillin, phenolphthalein, coumarine, etc., have practically doubled in price since the import restrictions were in force, the American Chamber of Commerce in London would respectfully suggest that licenses be more freely granted commensurate with the laws of supply and demand, as quantities now being manufactured here are far too inadequate to meet the demand."

Dye Imports.

The secretary reported that Mr. Mason, of the British Chemical Trades Association, had written the Chamber that his Association had appointed four members to sit on a joint sub-committee with four members of the Chamber's Advisory Committee on Drugs, Chemicals, and Dyestuffs, to investigate the methods and requirements of the Central Dye Importing Agency at Manchester, and to make recommendations on any features prejudicial to the interests of the importing and merchandising trades. The names suggested by the Chemical Trades' Association were as follows: Mr. William Mann (Mann and Cook), Mr. Hugh Griffiths (Griffiths and Talbot), and Mr. S. J. C. Mason.

Mr. Keene stated he would appoint three other members of the Advisory Committee to serve with himself on the proposed joint sub-committee. Their names and the whole idea could then be submitted to the Chamber's Executive Committee for approval.

PHOSPHATE INDUSTRY OF TUNIS.

H.M. CONSUL-GENERAL at Tunis writes as follows regarding the situation of the Tunisian phosphate industry:

Tunis comes second to the United States as regards the production of phosphates. Exploitation began in 1899, and in 1913 the production was over 2,000,000 tons. Tunisian phosphates can be classed under two categories: 58-63 and 63-68 per cent. of phosphate tricalcite with less than 2 per cent. iron and alumina combined. Before the war, sales of phosphates were quoted c.i.f. port of loading, and were dealt with by the head office of the exploiting companies for France, and by the agents of these societies in the principal importing ports—London, Genoa, Antwerp, etc.

The activity of the phosphate mines was greatly restricted during the war by lack of labour, high wages, lack of fuel and raw materials necessary for working and for the upkeep of underground galleries, new material, plant, etc. The requirements of sulphuric acid for war purposes increased gradually to the detriment of those factories manufacturing superphosphates. Together with this, the shortage of tonnage greatly impeded the supplies of those factories as regards phosphates and pyrites. The demand of agriculture, although reduced, has only been partially supplied, and that after considerable delay owing to the congestion on the railways. Moreover, the prices of superphosphates have been affected like those of most other commodities by a great increase, 30 francs per 100 kilos instead of 5 to 6 francs before the war.

A certain number of important markets in enemy countries were quite closed to phosphates and superphosphates. Moreover, neutral countries and even some allied countries have not been able to obtain the quantities they required on account of shortage of tonnage. On the whole, the demands for raw phosphates were less as regards tonnage than the demand before the war, but these demands could only be supplied within the limits of the tonnage available.

The following table shows the quantities of phosphates exported from Tunis according to countries in 1913 and in 1918.

	1913 Tons.	1914 Tons.	1917 Tons.	1918 (1st half-year) Tons.
United Kingdom ..	181,305	193,397	204,645	219,343
France	698,529	399,529	142,281	80,767
Italy	453,183	412,810	225,908	72,344
Portugal	40,404	36,508	12,730	—
Spain	52,985	49,295	16,315	4,960
Denmark	12,437	7,025	10,562	—
Other Countries ..	546,037	328,597	—	290
Total	1,984,880	1,427,161	612,441	377,704

As regards the direction of the exports, it will be seen that there were no exports to enemy countries, Belgium, Russia, Roumania, and Japan. Exports to neutral countries, after a slight decline in 1914-15, reached the figure of 189,000 tons in 1916, which is greater than that of 1913 (177,000 tons), on account of the greatly increased demand of Denmark (37,000 tons in 1915 and 77,000 in 1916, as against 12,000 tons only in 1913.) On account of the measures taken to limit the tonnage to destinations which might appear doubtful, the exports to neutral countries fell to 27,000 tons in 1917 and 5,250 tons during the first half-year of 1918.

Before the war, the two greatest consumers of Tunisian phosphates were France and Italy. As regards France, exports fell from 700,000 tons in 1913 to 142,000 tons in 1917. The first half of 1918 seems to show a slight increase with 81,000 tons. As regards Italy, the decrease was less acute—450,000 tons in 1913 and 205,000 tons in 1917,—and the first half-year of 1918 shows a very great decrease to 72,000 tons. The United Kingdom, on the other hand, increased her demands from 181,000 tons in 1913 to 205,000 tons in 1917, and the first half of 1918 shows a considerable increase to 219,000 tons. This result is due to the fact that the United Kingdom before the war imported great quantities of phosphates from Florida, and that for the moment she could only get her supplies from North Africa. It is, moreover, evident that the British market will now be more open to African phosphates than it was before 1913.

ITEMS OF INTEREST.

ARSENIC IN BORAX.—At the Wallasey Police Court on Friday of last week, Oliver Marsh, chemist and druggist, Liscard Road, was fined £1. and costs on a charge of selling borax adulterated with an excess of arsenic.

LEAD MINE EXPLOSION.—A serious explosion occurred last week at Rhandirmwyn Lead Works, Llandovery, Carmarthenshire, while the men were at work. One workman named Charles Beddison was killed, and another man was seriously injured.

NEWCASTLE CHEMICAL INDUSTRY CLUB.—The members of the Newcastle Chemical Industry Club have arranged for a field-day on Saturday, September 27, when Durham City is to be visited. Arrangements have been made for a programme of sports, including boating, golfing, and bowls.

SWEDISH EXPORT PROHIBITIONS RELAXED.—A Swedish Royal Decree of July 16, withdraws the prohibition formerly in force on the exportation from Sweden of a large number of articles as from July 28. The *Board of Trade Journal* of August 28 contains a list of the only goods the exportation of which from Sweden is now prohibited.

CHEMICAL WORKS EXTENSION.—At a recent meeting of the Aberdeen Dean of Guild Court plans were submitted on behalf of Messrs. John Miller and Co. (Sandilands Chemical Works) for permission to erect new cold-storage sheds at their premises. The plans were found to be all in order, and permission to proceed with the work was granted.

OILWORKS ACCIDENT.—Two of the employees—Robert Neilson, the manager, and William Faulds, a labourer, were severely burned on Monday in the premises of Messrs. Malcolm Graham and Co., oil refiners, 51, Wilkie Street, Glasgow. They were carrying a mixture of naphtha, pitch and resin when the fumes became ignited by the heat from a boiler furnace, the door of which happened to be open. The flames burned both men on the face, hand and arms.

DISPOSAL OF FRENCH STOCKS OF PERCHLORATE OF AMMONIA.—According to *Reuter's* Paris correspondent, a telegram from Bonneville states that a stock of 5,000 tons of perchlorate of ammonia, which represents a total value of £800,000., has been thrown into the River Arve, as the simplest way of disposing of it. Apart from the financial loss entailed by such a proceeding, the chemical has poisoned the river at least as far as its junction with the Rhone, killing all living things in the water.

NATIONAL PHYSICAL LABORATORY.—The Lord President of the Council has appointed Professor Joseph Ernest Petavel, D.Sc., F.R.S., M.I.Mech.E., etc., to be Director of the National Physical Laboratory in succession to Sir Richard Glazebrook, C.B., F.R.S., who retires on reaching the age limit on September 18 next. Professor Petavel is Professor of Engineering and Director of the Whitworth Laboratory in the University of Manchester. He is a member of the Advisory Committee for Aeronautics of the Air Ministry. He was educated at University College, London, and undertook scientific research at the Royal Institution and at the Davy Faraday Laboratory until 1898. He was elected John Harling Fellow of the Owens College, Manchester, in 1900, and was Scientific Manager of the Low Temperature Exhibit of the British Royal Commission for the St. Louis Exhibition, 1904.

SOUTH-WESTERN POLYTECHNIC INSTITUTE.—The South-Western Polytechnic Institute, Chelsea, S.W. 3, offers facilities for academic and technical education in many branches of chemistry and metallurgy. The department gives facilities for both day and evening courses, to meet the many requirements of these professions in London, including complete courses in general chemistry, metallurgy, and assaying requisite for the B.Sc. and A.I.C. examinations, and also technical courses. A feature of the laboratory work is the opportunity given for specialising in any particular branch of the above subjects, thus supplying much-needed facilities to men who have neither the time nor the necessity for attending a degree course. The various lecturers will be pleased to advise intending students with regard to selection of courses. The department is under the control of Mr. J. B. Coleman, A.R.C.S., F.I.C., F.C.S., and the aim of the Institute is to make its courses of sound practical use to those engaged in the chemistry industries. Further particulars may be obtained on application to the Secretary (Room 80).

ZINC AND ZINC DUST PRICES.—Prompt supplies are very short and the bulk of the business at present is for forward shipment from Australia. The prices of Australian high-grade zinc dust (88-92% metallic zinc) is unchanged at £68. to £70. per ton c.i.f. The price of Australian electrolytic zinc, containing 99-95% metallic zinc, remains the same, i.e. £42. per ton f.o.b. Australia for direct shipment to New Zealand, India, South Africa and the Far East.

EXPLOSION OF CALCIUM CARBIDE.—At an inquest on Thursday of last week, at Wallasey, on William Pattie, donkey man and storekeeper of the Cardiff collier *Relentless*, who was killed by an explosion on the vessel, it was stated that the explosion was caused by the deceased using calcium carbide in mistake for caustic soda for cleaning the ship's boiler. Another man, named Alderson, who was badly burned, is still in hospital.

FRENCH ACADEMY OF SCIENCES.—At a recent meeting of the French Academy of Sciences in Paris, MM. A. Gautier and P. Clausmann, in the course of a paper on "The Action of Fluorides on Vegetation," gave the results of some field-culture experiments. The fluorine in these experiments was added in the form of amorphous calcium fluoride; it was found to be favourable to the growth of wheat, oats, carrot, broad bean, cabbage, pea, poppy, potato, and hemp. No effect was observed with barley, rye, bean, buckwheat, and mustard, whilst beetroot, turnip, and onion were prejudicially affected by fluorides. MM. P. Sabatier and A. Mailhe communicated a paper on "The Catalytic Formation of Alkyl Chlorides, Starting with the Primary Alcohols." The authors stated that a mixture of hydrochloric acid and alcohol vapour, passed over alumina heated to 370° to 450° C., gives the alkyl chloride mixed with the ethylenic hydrocarbon produced by the dehydration of the alcohol. Primary, secondary, and tertiary chlorides may be formed in this reaction.

ACTION OF FERTILISERS.—Mr. J. B. Henderson, at a meeting of the Queensland section of the Australian Chemical Institute, gave a paper on the hypothesis which has been advanced by certain investigators to explain the action of fertilisers. It was pointed out that the generally held theory that fertilisers act solely as plant foods is unable adequately to explain certain observed facts, such as the richness of exhausted fields in fertilising elements, the immense quantities of plant food made available to roots by average agricultural soils, and the prolongation of fertility by the practice of rotation. In order to meet these facts, it has been suggested that fertilisers act as neutralising agents to toxic substances produced by the growing crop. Chemical bodies inimical to plant growth have been extracted from infertile soils; and further evidence is to be found in the phenomena of the adverse influence of weeds on cultivated crops, soil sickness, and the stimulating influence of small quantities of certain fertilisers. Tith and aeration play the part of rendering these bodies harmless to crops.

DRUG AND CHEMICAL WORKERS' CLAIM FOR HIGHER WAGES. A conference of employers and workpeople in the drug and fine chemical business was held in London on August 28, to consider the position in the trade, which had become acute. It was stated that a national settlement had been reached, and the following statement was made by Mr. P. C. Hoffman (organiser of the National Amalgamated Union of Shop Assistants, Warehousemen, and Clerks, one of the unions concerned):—"We have had an agreement with the Drug and Fine Chemical Manufacturers' Association for some considerable time in regard to wages and general working conditions. The gradings are as follows:—For men 21 years of age and over, class 1, 55s.; class 2, 52s. 6d.; class 3, 50s.; For women, 18 years of age and over, class 1, 40s.; class 2, 38s.; class 3, 35s. 6d.; class 4, 32s. 6d. Junior rates were for males under 15, 16s. 6d., up to 47s. at 20 years of age, and females under 15, 15s. 6d. up to 24s. 6d. up to 18. The employers have agreed to offer, as from August 1, apart from the 5s. advance on the minimum rates for adult males, a 5s. advance on the earnings of all male employees, except to those who are receiving 15s. above the minimum rates, and these shall receive such advances as will bring them up to 20s. above the minimum rates. We have not been able to come to any agreement with regard to any advance in wages for the women, but the unions concerned have agreed to recommend to their members to accept this offer of the employers, reserving to themselves the right to raise the question of the women's wages at an early date." The above settlement does not affect the members of the Society of Drug and Chemical Workers who were not represented at the conference.

NEWS FROM THE ANTIPODES.

[FROM OUR OWN CORRESPONDENT.]

SYDNEY, July 19.

Methylated Spirit Shortage.—A very unsatisfactory position exists with regard to local supplies of methylated spirits. For months past the public has experienced considerable difficulty in securing adequate quantities of this necessary commodity. The situation became acute towards the end of last year, and now, after a short period of temporary relief, another famine has arisen. There are over one hundred different trades in which extensive use is made of methylated spirits, and they are all suffering more or less severely from the present shortage of supplies. Unless the position is speedily relieved a serious dislocation of industry is feared, with consequent unemployment.

Sulphur as Fertiliser.—At a recent meeting of the advisory council of the Agricultural High School, Ballarat, the principal, Mr. Refshange, reported that an experiment in connection with the application of sulphur to one-eighth of an acre of potatoes grown on buck-shot land in the school farm had given very satisfactory results. The yield averaged about 13 tons to the acre, which was much higher than the ordinary crop from that class of land.

Importation of Dyes.—The Collector of Customs advises, with reference to proclamation dated February 26 last, prohibiting the importation of dyes other than those of British origin, unless with the consent of the Minister for Trade and Customs, that it has been decided to relax the restriction somewhat on the importation of dyes from foreign countries. Applications from importers for permission to import foreign dyes will be considered subject to the following conditions: (a) That an unsuccessful effort has been made to place the order for the dye (or an effective substitute therefor) with British manufacturers. (b) That the quantity for which permit is required shall not exceed the actual requirements of the importer or of the parties for whom the dyes are imported, up to December 31, 1919. In this connection figures should be given showing the consumption during, say, the last two years of the particular line in respect of which permission to import is sought.

Supplies of Potash.—In reply to a question asked in the House of Representatives, the Minister of Customs outlined the steps taken by the Commonwealth Government with a view to obtaining supplies of potash for the use of fruit growers and others. He said that since February last the question had formed the subject of numerous cable messages between the Government and the High Commissioner, who had advised that he was obtaining information as to prices from the French Government, who would control supplies of Alsatian potash. Prices at present were very high. A cablegram was sent recently to the High Commissioner asking him to advise the Government immediately supplies were available, and to quote quantity, grade, and prices. A reply had been received stating that Australian agents had been appointed, and supplies should therefore soon be obtainable through ordinary trade channels.

Higher Soap Prices.—Within the last few weeks local manufacturers of household and toilet soaps have raised their prices, owing—as their intimations to retailers have put it—to the increased cost of the raw material. This movement in manufacturers' costs has been most substantial in regard to tallow, quotations for which have moved sharply upwards at each successive weekly auction in Melbourne since the British Government withdrew the war-time restrictions from the London market. In that centre there was material enhancement, and as provision has been made lately for freight for a fairly considerable quantity of Victorian make for the United Kingdom, there has been a variation in prices in practically all of the Australian selling centres in the direction of a parity basis.

Chemical Market.—Chemicals are still irregular in parcels, but there is said to be a noticeable strengthening in values for many lines. Reports from England and America show that stocks could not be landed for anything like the rates quoted locally for a great majority of lines. The following is a list of distributing prices, and parcels were to be had at reductions in most cases:—Alum: Japanese £30., English £33. per ton. Arsenic: White £65., grey £60. per ton. Bluestone: Macleodfield's £54., Japanese £44., U.S.A. £50. per ton. Boracic Acid: £96. per ton. Borax: Powdered or lump, £55. per ton. Carbide: Japanese, 34s. per 100 lb. drum. Carbon Bisulphide: Colonial, 10d. per lb. Carbolic

Acid: English, 98%, 9s. 6d.; Colonial, 9s. per gallon. Citric Acid: 3s. 6d. net, per lb. Tartaric Acid: 3s. 3d. net, per lb. Cream of Tartar: 95%, 3s. 1½d.; 99%, 3s. 1½d. per lb. Cyanide: 98%, 1s. 3d. per lb., in one to four case lots. Quick-silver: 6s. per lb. Resin: G grade £36. per ton, N grade £40. per ton. Soda: Silicate, liquid, £26.; bicarbonate, in kegs, £15.; soda ash, £15.; soda crystals, £9. 10s.; caustic soda, English, 70-72%, £30.; 76-77%, £33. per ton. Sulphur: American flowers, £36.; Japanese, common, £18. per ton. Oxalic Acid: 2s. 9d. per lb. Chloride of calcium: £20. per ton.

THE COLOUR OF INORGANIC COMPOUNDS.

THE study especially of organic compounds, derivatives of which can be prepared in endless varieties, points to a connection between structure and colour. Though the nature of that connection is by no means understood, there is a good deal of evidence in favour of the view that the electrons involved in selective absorption—which, when in the visible spectrum, gives rise to colour—are the same electrons which take part in the chemical union of elements, that is, the valency-electrons. Some elements like the alkali metals are only credited with one, non-variable, valency; to other elements variable valencies are assigned, three or five, e.g., to nitrogen, and one of these valencies is considered the "normal valency;" but there is considerable disagreement as to this normal valency and to the possible variable valencies. We know little about the forces determining the stability of the electronic arrangements, i.e., the forces which resist small displacements of the electrons from their equilibrium position. Those forces will, however, be a measure of the resistivity of a compound, which is connected with the possibility of an element's existing in different valency-states, but which has no direct connection with the thermodynamic stability of a compound or of a valency-state; that thermodynamic stability is measured by the total work necessary to separate the parts of a molecule.

According now to the magneton theory of the structure of the atom, proposed by Parson and chemically developed by G. N. Lewis, there is for all atoms—except those of hydrogen and helium, which stand apart—one particular arrangement of the electrons which has maximum stability. In this arrangement the number of electrons, grouped around the positive nucleus or in it, is either 8 or 0. All other arrangements of electrons, consisting of 2, 4, 6, 10, and to a still greater extent, arrangements of odd numbers of electrons, are less stable. To understand the colour rules which F. Russel von Bichowsky has deduced from these special atoms of Lewis (*Journal of the American Chemical Society*, of March 1918, and later issues) we should first give a few of the "normal" valencies: Sodium, copper and silver, as well as fluorine, have the normal valency 1; mercury, 2; thallium, 3; tin, 4; nitrogen, 5; oxygen, sulphur, tungsten, 6; chlorine, bromine, iodine, 7; iron, manganese, nickel, platinum, 8. Thus chlorine would be surrounded by seven dots, if a dot represent an electron, sodium would have one dot, and in sodium chloride the chlorine would be symmetrically surrounded by eight electrons (two dots on each of the four sides.)

A substance like sodium chloride has maximum stability and zero colour, (i.e., it is colourless) according to Bichowsky, the selective absorption being confined to the invisible ultra-violet. Titanium has several valencies and gives the chlorides $TiCl_3$, $TiCl_2$, $TiCl$, the first colourless, the second yellow (absorption in the violet), the third blue (absorption in the red.) In these chlorides the electron groups round the titanium atom contain 6, 4, 2 electrons respectively, and the general rule is that in salts of the same elements the colour changes from colourless to yellow, green, blue, violet, black as the groups vary from 8 to 6, 4, 2 and 1, 3, 5, 7, or in that order. The atom-colour of every element itself in its normal state is zero, and compounds of the non-variable valency atoms are likewise colourless; when the valency is variable, the colour turns more blue when the valency changes from the normal; thus the copper fluoride CuF is colourless, the CuF_2 is blue. The colours of compounds are sometimes merely additive; sometimes the colour may be more blue than the sum of the colours would indicate. The colours of the elements themselves are those of their ions, and not many elements are sufficiently known in the ionic state. The rules proposed by Bichowsky are not simple; but the arguments are suggestive, especially also as they concern inorganic as well as organic components. —*Engineering*.

BRITISH ASSOCIATION OF CHEMISTS.

"If we don't hang together we shall assuredly all hang separately."
—JOHN HANCOCK, when signing the Declaration of Independence.

Hon. Registrar: DR. FRANCIS W. KAY,
Chemical Department, The University,
Liverpool.

NOTICES.

NOTICES and reports from secretaries of local Sections and articles and correspondence for these pages should be sent to the hon. editor, Dr. E. H. Rodd, 7, Mauldeth Road West, Withington, Manchester, and not to the *Chemical Trade Journal and Chemical Engineer*.

The hon. editor will be glad to receive short articles on the views of members with respect to the B.A.C., its aims and aspirations, for publication in these pages. Such articles should be accompanied by the name and address of the writer, not necessarily for publication.

Reprints of the proceedings of the British Association of Chemists as published in the *Chemical Trade Journal and Chemical Engineer* can be obtained from the hon. editor on payment of an annual subscription of 4s.

Applications for membership of the B.A.C. should be sent to the Registrar, Dr. F. W. Kay, not to the Editor.

ADDRESSES WANTED.

Name.	Late address.
Gee, F. H., B.Sc.:	86, Ridgeway, Edgbaston, Birmingham.
Gee, J. H., B.Sc.:	93, Common Lane, Wood End, Birmingham.
Guild, E. J.:	Thornhill Villa, Maidstone, Kent.
Maxfield, H. L.:	54, Glasgow Road, Cheetham Hill, Manchester.
Wilson, A. B.:	Edon Villa, Victoria Avenue, Borrowash, near Derby; and Airedale, Ferryside, Yorks.

Notifications of change of address should be sent to the Registrar, and not to the Editor.

THE PROCEEDINGS OF THE ASSOCIATION.

The Council.

A meeting of the Council was held on Saturday, August 23, at the St. James's Hotel, Derby, Professor J. W. Hinchley in the chair.

Nominations Committee.—On the recommendation of the Nominations Committee, seven candidates were admitted full members, ten as probationers, and six as students. The names were also submitted of 56 candidates for membership, 17 for probationership, and one for studentship, whose applications had been scrutinised and approved by the local assessors, and these were referred to the Nominations Committee for their final decision.

Whitley Councils Committee.—This Committee reported the results of the Conferences that had been called at its initiation to bring about concerted action amongst scientific and technical organisations in order to secure proper representation on Whitley Councils. The invitations were extended to scientific and technical associations organised on a professional basis, and were accepted by the National Association of Industrial Chemists, the British Association of Chemists, the Oil and Colour Chemists' Association, the National Union of Scientific Workers, the Society of Technical Engineers, the Electrical Power Engineers' Association, the Junior Gas Association, and the Association of Engineering and Ship-building Draughtsmen, the last-named, however, retiring after the first conference.

The attempt was first made to bring about a Federation of Chemical Organisations, and a similar one of Engineering Organisations, with a view to finally uniting them in one common larger federation. This, unfortunately, failed, in consequence of the difficulty of including one of the constituent associations in the scheme, and it was eventually decided to adopt the principle of a general federation of all the associations.

As, however, during the course of the negotiations certain constituent societies attending the conferences took concurrently the first steps towards forming amongst themselves a federation with the same aims, it was eventually decided to accept this as a nucleus, to request it to publicly advertise for adherence on a trade-union basis, and to meet on September 6 to establish the constitution of a General Federation. The Council nominated a Committee of five members to attend this meeting.

Munitions Chemists' Case.—The President read correspondence which had taken place between the Association and the

Labour Party, and which had led to the matter being ventilated in the House of Commons, as reported in the issues of this *Journal* (August 9, page 150, and August 16, page 173). These replies were considered unsatisfactory, and it was decided that the matter should be followed up when Parliament reopens.

The help thus given was very much appreciated by the Council, and it was resolved that a cordial vote of thanks should be sent to Messrs. Clynes, Sith, and Young, and also to the Labour Party, who had taken such an interest in the matter.

The subject is further commented upon in a separate article in this issue.

Widnes Election.—It was decided that questions on the attitude of the Government to chemists and on the chemists' interests generally should be submitted to both candidates, and the replies published through the Press. These will be found on a later page of this issue.

Salaries.—A scheme of salaries drawn up after consultation with the Sections was unanimously adopted, and it was decided to issue it as a confidential document for the information of the Association's officials. Following up a resolution proposed by the London Section, the Council approved that in the propaganda work of the Association the only salary mentioned should be a minimum salary for a fully qualified and experienced chemist of £350. per annum.

Propaganda.—A circular setting forth tersely the primary objects of the Association and underlining its economic aspects was approved, and 4,000 were copies ordered for circulation along with the address of Mr. Todd on the Whitley Councils Scheme.

Price Advertisement.—A letter was read to the Council, received from a professor of standing, stating with respect to the £100. advertisement for a chemical process that he had been asked to adjudicate upon it, but that he had refused to do so, as it was possible that the action might be regarded as an attempt to exploit chemists. The Council expressed their appreciation of the attitude thus taken.

Treasurer's Report.—A statement was submitted by the Treasurer showing the Association to be in a sound financial position, and with a substantial balance in its favour.

North-East Coast Section.—Steps were taken to further the organisation of this Section. Chemists in this district are invited to communicate with Dr. J. H. Paterson, The Green, Walsend-on-Tyne.

Guarantee Fund.—It was decided to raise a Guarantee Fund for propaganda work, including the payment of an Assistant Secretary, and the matter was left in the hands of the President.

Subscriptions.—It was resolved that as the financial year will shortly close, subscriptions from applicants from the present date should be counted as subscriptions for the coming year.

Other Business.—Progress was reported in the matters of Trade Union Registration, Income-tax Rebate, formation of an Admiralty Chemists' Group, and the re-establishment of the Edinburgh Section. The attention of the Council was also directed to the action of the military authorities in transferring men from the Chemists' Brigade to other units for the purpose of subordinate and routine work, and it was decided to follow the matter up.

The next meeting of the Council will be held at Derby on September 27 at 1.30 p.m.

SALARIES OF CHEMISTS IN GOVERNMENT SERVICE.

The history of the agitation on the part of chemists in Government munitions factories during the past few years should be impressed on the minds of all chemists. The chemist trained the operatives, coached the foremen, raised and maintained efficiencies, improved processes and plants, and responded to every call made on his brains and service with extraordinarily successful results.

Although the Government began to discover the value of the "chemist" as a chemist, the fact that he was a living man who required a living wage, adequate to the position he occupied, made no impression. The Ministry of Munitions refused to accept the obvious principle that "for purposes of efficient factory control and the maintenance of discipline an official should be paid more than individuals for whose work he is responsible and whom he controls." A considerable percentage of operatives and tradesmen employed were paid more than the chemists.

The memorial, stating the position and signed by 352 chemists in nine Government factories, which was sent to the Ministry, does not appear to have been acknowledged, but

the chemists were informed, through the Superintendent of Gretna Factory, that "the salaries of chemists cannot be compared with the earnings of tradesmen"; and that "the Ministry object to meetings being held by any section of the staff of factories under their control to pass resolutions asking for revision of salaries and appointing deputations to wait on the Superintendent in respect thereof." Truly an extraordinary statement on the part of a Government actively engaged in forming Whitley Councils, etc., and publicly advocating collective bargaining. On November 16, 1918, these chemists addressed the Minister of Munitions himself, the Right Hon. Winston S. Churchill, and an expression of regret has recently been made in the House of Commons for his neglect to reply to this letter.

The British Association of Chemists have secured the interest of the Labour Party in this subject, and a number of questions have been put in the House of Commons by Mr. Sith and Mr. Robert Young. A study of these questions and answers is interesting. It will be noticed how questions involving important principles are dealt with by politicians, and how a display of power compels the Government to recognise principles of "right" instead of "expediency."

It is satisfactory to know that the Government now throw overboard the statement made through the Superintendent of Gretna Factory, and say that it "must not be taken to express the considered view of the Ministry," but nevertheless they do not state what that "considered view" really is.

We do, however, now learn that a Committee of the Treasury has been formed to consider the question of the salaries to be offered to scientific and technical officers of the Government, but there is no suggestion that the arrears due to Government neglect of the matter will be paid.

Again, Mr. Hope, on behalf of the Government, puts forward an untenable proposition when he states that "even after making full allowance for the increased cost of living, the scale of salaries paid by the Department can be compared favourably with the salaries paid by private firms under pre-war conditions." This is an unfortunate statement for a Government official to make. Is not Mr. Hope aware that the salaries paid to chemists under pre-war conditions were generally disgraceful, and constituted a pointed indication of the backwardness of chemical industry in this country? He should know that it is necessary to attract the best brains to the service of chemistry if the industrial efficiency of the Empire is to be maintained, and that this cannot be done by paying the chemist the wages of a labourer. He ought to know, also, that the Government should set an example in such matters, and not excuse itself by following the practice of private firms who are swayed only by commercial considerations.

The matter cannot be allowed to rest with the evasive and illusive replies so far given on behalf of the Government. What is the "considered" opinion of the Government? When is it going to give effect to its "considerations"? Are these "considerations" going to act retrospectively?

THE BRITISH ASSOCIATION OF CHEMISTS AND THE WIDNES ELECTION.

In view of the importance of the chemical interests in the Widnes district the Council of the B.A.C. thought it proper to ascertain, for the guidance of its local members, the attitude of the two candidates on matters of vital interest to the chemical profession.

The Hon. Local Secretary of the Liverpool Section therefore placed before Mr. H. M. B. Fisher and Mr. Arthur Henderson the following questions:—

Are you prepared to secure by Parliamentary action or any other constitutional method:—

- (1) For chemists in Government employ—
 - (a) The right to negotiate as a collective body.
 - (b) Salaries commensurate with their services to the State.
 - (c) Corresponding increases in salary in the event of any future increases in the operative rate of pay.
- (2) The redress of the wide discrepancy now existing between the totally inadequate salaries paid to the majority of industrial and academic chemists and the wages received by skilled artisans.
- (3) That no public contract shall be given to firms employing chemists at less than the minimum scale of salaries fixed in a constitutional manner by the Association.

- (4) The amendment of the Patent Laws in such a manner as to prevent the unfair exploitation of the true inventor by his employer or the capitalist.
- (5) That all agreements to transfer patents without fair payment to the inventor shall be null and void.
- (6) As a practicable solution to the two latter propositions, and in order to protect the public from the aggressive monopolisation of patents by firms who do not intend to work them, the creation of a Licensing Department of the Board of Trade, which shall be conducted on the lines, say, adopted in dealing with enemy patents during the late war—namely, by granting licences to more than one manufacturer to work one and the same process, and adequate royalties to the inventor in every case.
- (7) As a development of the progressive democratisation of industry now initiated by the establishment of Industrial Councils, that chemists shall have an equitable share in the joint control of industry by capital and labour.
- (8) That the name "Chemist" be legally re-defined.
- (9) That steps be taken to establish a Statutory Register of all those who are qualified to practise chemistry in the British Empire.
- (10) That legislation be obtained to safeguard the public by securing that certain prescribed chemical operations shall be under the control of a chemist.

The following replies have been obtained:—

Mr. Fisher: "I approve of 1, 2, 4, 7, 8, 9, and 10. On 3, 5, and 6 want more information before committing myself."

Mr. Henderson: "I beg to state that as the proposals are so much in harmony with the general policy of the Labour Party, I have no hesitation in giving my assent to them all."

The questionnaire and the above replies were communicated to the local Press.

PROTECTION FOR JAPANESE CHEMICAL INDUSTRIES.

THE following resolutions calling for protection have been passed by a Committee of the Japan Chemical Industries Association, and communicated to the Japanese Government:—

1. An import duty of yen 5 per 100 kin to be imposed on potassium chlorate, provided no duty is imposed on potassium chloride.
2. Import duty on caustic soda to be 25 per cent. Price of salt to be reduced to 40 sen. Exports of bleaching powder to be subsidised at the rate of yen 1 per 100lb.
3. The post-war cost of the manufacture of soda ash may be estimated as yen 115.77 (? per ton), and it is requested that the Government take steps to protect the industry, as prospects are not entirely hopeless.
4. The present import duty of 5 per cent. on "intermediate" chemical manufactures—i.e., those which are neither dyestuffs nor drugs—should be revised.
- A duty of 25 per cent. *ad valorem* to be imposed on raw materials, such as benzene and methyl alcohol; on salvarsan and compounds of arsenic, yen 4 per gramme.
5. That the Government-protected factories should not take up the manufacture of products successfully manufactured by private concerns.
6. The Government should establish regulations for granting subsidies to exporters of chemicals, and arrange for rebates of insurance and freight charges.
7. If import duties on zinc and lead be increased at any time in the future, a rebate should be given when these materials are to be used for the manufacture of paint or cosmetics.

MERCURY PRODUCTION IN THE UNITED STATES.—According to statistics compiled by F. L. Ransome, of the United States Geological Survey, the mercury production of the United States during the first quarter of 1919 very distinctly showed the lessened demand for mercury with the end of the war, both in the production figures and in the prices. The total production amounted to 5,960 flasks, against 8,674 flasks in the same period of 1918. The prices had steadily been sinking, from 103.75 dollars in January to 90 dollars and 72.80 dollars in February and March, but were still higher than in pre-war times, though not high considering the general rise of prices.

LEGAL INTELLIGENCE.

Chemical Merchant's Heavy Losses.

At the London Bankruptcy Court last week, the first meeting of creditors was held under the failure *re* Joseph Algernon Hare Duke, residing at the "Dell," Croft Road, Sutton, and Henry Slater, residing at "Ingles," Burdon Lane, Cheam, Surrey, and carrying on business as Perry, Mills and Co., 61 and 62, Gracechurch Street, E.C., chemical merchants.

Mr. F. T. Garton, Official Receiver, stated that prior to 1908 the debtor Duke was a half commission man on the Stock Exchange and from 1908 to 1912 he was managing director of Oil Refineries Ltd., at a salary of £700 per annum. In 1912 he commenced business in partnership with a Mr. Perry, under the style of Perry, Mills and Co., at 29, Gracechurch Street, E.C. They had no capital and none was required, because their business consisted chiefly of agencies. They secured a number of agencies for German firms and worked up a very successful business, but upon the outbreak of war a considerable part of their business disappeared. In 1913 his brother joined the firm, but withdrew on the outbreak of war in 1914, when he rejoined the Army. Mr. Perry and debtor continued the business until September, 1917, when the former withdrew from the firm and a dissolution of the partnership was gazetted. In August, 1918, he opened an office at 67, Hanging Ditch, Manchester. It was originally intended that that office should be used as a buying office, but it gradually developed into a branch business. In September, 1918, Mr. Slater became a partner in the firm, and he put about £700 into the business. The firm had chiefly dealt in chemicals which were exported to the Continent. They had several large contracts with Italian firms, but on the signing of the Armistice those firms refused to take further deliveries on the ground that the Armistice terminated all existing contracts. That placed the firm in a very awkward position, because they had purchased very large quantities of chemicals for export, and their bankers had made advances on the warrants. Since then the markets had gone against them, with the result that the prices had fallen considerably below what they had paid for the goods. They were however making claims against four Italian firms for damages for breach of contract, amounting to something like £14,800. The debtors estimated their liabilities at about £11,000, and the assets at about £2,000, but they could not value their assets exactly because they did not know how much would be received under their claims for breaches of contract. The debtor Duke had a half share in a farm at Headley, near Epsom, but it was only a leasehold property. The failure of the firm was attributed to the Italian firms refusing to accept delivery of the chemicals under the contracts entered into before the Armistice.

In reply to a creditor, the Official Receiver said he had not received any notice of an execution being levied on the debtors' goods. Eventually it was decided to appoint Mr. Claude Leigh Sixsmith, chartered accountant, of 6, Broad Street Place, E.C., as trustee of the estate to act in conjunction with a committee of inspection, consisting of Mr. Clarence Hadfield, of the Nippon Shoko Co. Ltd., Mr. R. A. Giles, of the Brimsdown Lead Co., and Mr. W. R. Livesey, of Messrs. Riley and Sons, Ltd.

A question arose as to how much the stocks of chemicals were likely to realise, and Mr. Hadfield suggested that the prices had gone down to about 60% or 70% of the prices ruling before the Armistice.

Mr. Hawkins, who appeared on behalf of a creditor, said he did not think the stocks held by the banks would realise sufficient to pay their advances.

In reply to a creditor, Mr. Duke said they had received certain unjust claims by Australian creditors against them, but he did not know if they were going to be put forward.

Mr. Hawkins, who appeared for the Brimsdown Lead Co., suggested that the trustee's bond should be fixed at £2,000, with an undertaking to increase it, should he receive more assets at any time. The Official Receiver accordingly fixed the bond at that amount and the remuneration of the trustee was left in the hands of the committee of inspection.

A Debtor's Huge Surplus.

At the London Bankruptcy Court on Tuesday, before Mr. Registrar Francke, the public examination was appointed to be held of Francis Joseph De Giers, 3, Cross Lane, E.C., and Aspen House, Sudbury, Middlesex. The statement of affairs filed by the debtor disclosed gross liabilities amounting to

£18,440. 18s. 8d., and assets estimated to produce £111,464. 18s. 9d., thus showing an estimated surplus of £93,024. 0s. 1d. Upon the case being called on for hearing, the Official Receiver stated that the debtor had only filed his statement of accounts on August 27 last, and he had not been able to issue his usual report and summary of accounts to the creditors, therefore he asked that the case might be adjourned until October 29.

Mr. Tindale Davis, who appeared on behalf of the debtor, offered no objection, and the case was adjourned accordingly.

The receiving order was made on July 8 last, and the debtor, an American citizen, came over to this country, in 1912, when he became connected with a syndicate for the purpose of trying to sell oil properties in London. He remained in England until July, 1914, when he returned to America to complete certain business, but soon after his arrival there, war broke out, and the deals fell through. Early in 1915 he was asked to take up the European agency for the New England Supply Co., of Providence, Rhode Island, U.S.A., his remuneration being a certain allowance for expenses, and 5% commission on all business done in Europe. He took offices at 6a, Finsbury Square, E.C., for the company. Under his arrangement with the firm, he was not to receive any commission until peace had been ratified, although, roughly, his commission amounted to £100,000. In May, 1918, he promoted the Anglo-Spanish Trading Company, Ltd., with registered offices at 3, Cross Lane, E.C., for the purpose of carrying out certain olive oil contracts, and to carry on a general produce business. He was appointed managing director, and was allotted £2,000, in shares. The company was still carrying on business, and the shares should be of some value. He had promoted other companies, all of whom owed him money in regard to advances made to them. He did not admit being insolvent, but his present financial difficulties had arisen through his inability to collect commission due to him from America, and to his liability in regard to loans made to various companies in order to keep them going.

ZINC OXIDE MANUFACTURE.

WRITING in *The Times* of Saturday last, Mr. Alexander J. McConnell, in the course of a letter dated August 29, said: The Board of Trade prohibit the importation of zinc oxide excepting under special licence, and they stated in writing yesterday that such licences are granted only to regular importers based on their direct importation during the year 1913. A leading British manufacturer desires to use a high grade of zinc oxide which is not at present being manufactured in this country, but which to him is an essential raw material in the production of an article in which he can do an extensive export business. He is unable to obtain supplies, and must go on using an inferior material unless he puts himself into the hands of a merchant who happened to be importing zinc oxide in the year 1913. It seems incredible that sample lots of the highest known grade of zinc oxide are lying at an English port unable to be touched by one of our manufacturers even for experimental purposes. But such is the case.

On Tuesday Mr. J. K. Campbell replied to the above letter in the following terms: In *The Times* of August 30 Mr. Alexander J. McConnell states that a British manufacturer desires to use a zinc oxide which is not being manufactured in this country, and that he is unable to obtain supplies. I would like to point out that the highest grade of zinc oxide is being manufactured on a large scale by an old-established English firm. The purity and colour of this product is equal to the highest grade of imported zinc oxide. Many qualities of zinc oxide inferior to the one above referred to are being used by druggists with satisfaction to-day. It would be a pleasure for me to put "the British manufacturer" in touch with a British manufacturer of pure zinc oxide, and I am sure he would not wish to buy in a foreign market in future.

ANILINE DYE IMPORTS AT HONG KONG.—H.M. Commercial Secretary at Peking states that during the January-March quarter of this year aniline dyes were imported into Hong Kong to the value of £18,774., as against less than £7,000 for 1918, but some merchants question the accuracy of the latter figure. American firms are devoting much attention to this business, and by the distribution of samples and practical demonstrations of the method of using their products, are steadily improving their position in the market.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Nitrate of Soda.—There is practically nothing doing, the article being of no immediate interest as a fertiliser, while chemical manufacturers buy only from hand to mouth the small quantities required, prices ranging from £22. to £24. per ton, according to ports. No full cargoes have arrived in the United Kingdom, the imports being confined to parcels by "liners" from Chili. A few steamers have been fixed at very high rates for the Continent, presumably in connection with the sales made by the Chilean Government for account of producers outside the Association, but the latter, through asking higher prices, is still out of the market on the West Coast; its programme for the disposal of nitrate on this side next season will no doubt soon be revealed, and it will be interesting to see the prices fixed in competition with the synthetic nitrogenous products now officially acknowledged to be in the field against natural nitrate of soda. As shown by the report of Dr. Edward C. Worden (United States Government expert), quoted in our issue of August 23, the German Badische Aniline Company is in one factory alone about to turn out under the Haber process over 800,000 tons per annum of sulphate of ammonia; this, without counting the works already in operation and other forms of nitrogen, will not only supply all this country's agricultural requirements of the kind, but will leave large quantities available for export. The Nitrogen Products Committee—the issue of whose report, dated May last, still awaits a definite instruction from the Ministry of Munitions—consider the Haber process "feasible," and the Board of Agriculture has just decreed an important increase in the prices of sulphate of ammonia to the British farmer. Well may the latter, worried to death by official interference, ask to be preserved from his friends!

North African Phosphates.—The phosphate position in North Africa is fairly illustrated by the experiences of the Gafsa Phosphate Company, which is one of the leading companies in North Africa. Unfortunately, difficulties in respect to labour and scarcity of freight interfered seriously with phosphate business generally during the war, necessitating a reduced production and exportation. This latter, which constitutes the governing factor in the activity of the company named, being now under improved conditions, the production, it is expected, will develop rapidly. At the end of 1918, when the Allied Governments made their control of freights less rigorous, this company was able greatly to increase its shipments, which made by the end of the year 720,193 tons, or 50 per cent. better than the preceding year. As has already been noted, the French Government are making great efforts to put additional tonnage at the disposal of the North African phosphate companies, all of which have suffered from disabilities identical with those that affected the Gafsa, and will correspondingly benefit with it from the improved conditions now obtaining.

Basic Slag and Superphosphate.—Basic slag is in good seasonable demand, but it is feared the recent coal strike will have somewhat interfered with the production. Prices are without change, as also are the superphosphate quotations. Higher prices for slag are spoken of, and some increase in values would not be out of the way, it is argued, and would not appreciably interfere with consumption.

Norwegian Nitrates for Poland.—Norway and Poland are getting into direct business relations, particularly, it appears, in respect to the products of the nitrate works. A delegation from the Norwegian nitrate producers has gone to Poland in order to organise an exchange of goods, which, in regard to Poland as an exporter, would consist mainly of coal, oils, etc. It is hoped to establish an agreement of some importance and duration for shipments to be made and received reciprocally through Dantzic and Christiania.

Sulphate of Ammonia.—The expected price increases for 24½ per cent. ammonia delivered to buyer's nearest station or wharf in Great Britain, prompt cash payment, have now been announced. They are £20. 10s. for October, £20. 15s. for November, £21. for December, £21. 7s. 6d. for January, £21. 15s. for February, and £22. for March, April, and May next year. The average export figure appears to be about £25. per ton, net cash, in double bags, f.o.b., British port, but not a great deal of business is passing in that direction. Generally, it seems that more sulphate of ammonia is wanted here than can be secured for the time being. Probably the coal strike has had a great deal to do with this decrease in supply, and some time must elapse before that setback has

been recovered from. Fears are expressed that America is going to eat very substantially into overseas markets for sulphate of ammonia formerly supplied by Great Britain. It cannot be said, however, that up till now there have been very strong signs of this taking place, and the latest export demand movements in America are only marked moderate.

Atmospheric Nitrogen.—Although some despondent views have been expressed about the large Government factory on the Tees, which was started last year for the fixation of atmospheric nitrogen, it appears that the scheme is not to be the loss that some writers have been presuming. The matter is not yet decided, but important negotiations are now said to be in progress whereby the whole undertaking will be handed over to an exceedingly busy and wealthy combination of manufacturers of explosives and chemicals. This arrangement would relieve the Government of all liability for the undertaking. It will be stipulated that the Government shall have the right of first call upon the output of air nitrates in the event of any national emergency. A great deal of very useful research work has been done by the Nitrogen Products Committee. This is a British Government organisation which was brought into being while Mr. Lloyd George was Minister of Munitions. It is composed of scientific experts, and includes among its members many eminent men. Its object was originally to investigate and report on various matters primarily relating to the fixation and utilisation of atmospheric nitrogen with a view to facilitating the manufacture of nitric acid and its derivatives for munition purposes.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

The tinplate trade is much better and there are now 112 additional mills operating compared with a year ago. At the present moment there is a lack of skilled rollermen, doublers, and furnacemen, and outputs are thereby handicapped. Relative to the outstanding question of the 12½ per cent. demand of the operatives, the arbitrators have failed to agree and the matter will now have to be placed before Mr. Marley Samson, K.C., the independent chairman appointed.

The patent fuel industry remains very active and export orders are coming in faster than the trade can conveniently deal with. The expansion of foreign markets is rapidly taking place.

An important cargo of 2,695 tons of phosphate from Sfax reached Newport on Monday.

The exports of chemicals from South Wales ports are just now of a very meagre character, and the home requirements with the exception of fertilisers are not so pressing as they were a week or two since. The coke ovens are working well and sulphate of ammonia production is quite as great as, or even greater than, before the war. Fortunately, the demand for coke is considerable, and good shipments have been sent during the week to the Argentine, St. Malo, and Dieppe.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

The decrease in coal production caused by the shorter hours is estimated to be 15 per cent., and is causing serious inconvenience to coke makers. Although the by-product ovens are not working at more than two-thirds of their capacity, it is, nevertheless, impracticable at the present time to secure an adequate supply. As long as the hematite pig-iron trade preserves its present strength, coke makers are assured of the absorption of their make. What does give rise to anxiety, however, is a prospect of a slackening of demand for ordinary iron. There is a ready market for low-phosphorus brand of iron, but it is undoubted that several furnaces on ordinary iron will have to be damped down unless the demand for Bessemer rails quickens. On the whole, the signs are not discouraging. Continental users cannot get their wants properly coped with by American steel-makers, and it is believed that, in spite of the high prices, they will be compelled to come to England with their business. If this should prove to be a correct view of the situation, it is obvious that coke-makers will be faced with a busy winter. East Coast coke supplies to the Furness district this week are 15,100 tons, and to West Cumberland 9,000 tons. The demand for Lenzole, whether from Ireland or from local users, is brisk; sulphate of ammonia is required by home users; and there is a good market for pitch.

REPORTS OF COMPANIES.

Ammonia Soda Company, Ltd.

At the meeting of the Ammonia Soda Company, Limited, held at Lostock Gralam, near Northwich, on August 28, Mr. John H. Wilcox presided. At the ordinary proceedings the report was adopted, and a 6 per cent. dividend on the preference shares was declared.

An extraordinary general meeting was held afterwards at which a resolution was proposed that the company go into voluntary liquidation.

Mr. Henry Ellison, of Bradford, proposed, and another shareholder seconded an amendment that an independent expert be appointed to examine the company's plant and report to the shareholders, the name of Mr. Stanley Smith, of Chancery Lane, London, being suggested as this expert. This amendment was lost, and the substantive resolution carried.

Before such resolutions Mr. Ellison asked several questions, to which the chairman replied, admitting that Brunner Monds held by far the major part of the capital of this company, that Brunners had written to the latter requesting them to go into liquidation, that prior to the present notice no other shareholders had been consulted, that the current directors were all former or present officials of Brunner Monds, and that the brine wells had been dismantled with the view of preventing possible contamination of the brine supply of the two concerns by calcium chloride liquor.

The Chairman said this had been done upon the advice of Mr. Stanley Smith, who made the proviso that Brunner Monds should supply the Ammonia Soda Company with an unlimited supply of brine from other sources.

Hereupon Mr. Smith asked whether this proviso would stand good in the event of any other concern than Brunners taking over the Ammonia Company.

The Chairman could not answer for that, but upon being asked whether the directors of the Ammonia Soda Company had been advised by former or present officials that with certain alterations and extensions of plant the business of that company might be made highly profitable, he replied that originally the directors had been so advised, but subsequently they took what they considered better advice. Answering the question whether before deciding upon liquidation the directors would consult the minority shareholders and reconsider the position, the Chairman replied that the shareholders were being consulted by the present proposal to liquidate the concern.

Asked whether the business of the company was not a highly profitable business, and whether there was any reason why by good management the business of the Ammonia Soda Company could not be made highly profitable, the Chairman replied that in the opinion of the directors it was not highly profitable. The question whether Brunners did not stand to benefit substantially by the liquidation of the Ammonia Soda Company was ruled out of order.

English Oilfields, Ltd.

An extraordinary general meeting was held in London on Monday to increase the capital of the company to £1,500,000. Sir James Heath, Bart. (chairman of the company) presided.

The Chairman stated that the directors proposed in the first instance to make an issue of 400,000 of the new shares and to offer them at the price of 25s. per share in the proportion, or as near as possible so as to avoid fractions, of four new shares for every three held by each shareholder.

Dr. W. Forbes-Leslie, in seconding the resolution, said: This company was issued July, 1918. It acquired the interests of the English and Foreign Oil Finance, Ltd., its land interests, and the technical information of the district in which these properties were situated. The land area it secured was important. It covered about 20 square miles of land, especially selected as a result of very extensive geological investigations carried out for several years previous to the issue of your company. No more land within the selected limits of the field is now obtainable; we have covered it. We have found that mining in the shale series is economical and cheap, roofs and floors being available and the structure of the seams giving natural facilities for mining. Samples from the mine faces on the whole have demonstrated that in thickness of seams measured up from drill records we have been about 25 to 30 per cent. less than shown in the mine, that in volatile contents as given from laboratory tests on cores we have been over 50 per cent. less than freshly mined samples

of the same beds demonstrate. This is so much to the good. Another point of the most vital importance has been further demonstrated in mining. The oil obtained from the middle shales is an oil of remarkable quality, practically free from sulphur, and yielding many valuable by-products, and especially rich in motor spirit and wax. This discovery, first made in mining operations and finally worked out in the laboratory and in commercial tests, transformed at once the whole business into one of first-class importance. I originally estimated commercial production at 30 gallons per ton, but in consequence of the yield from mined middle shales being so much richer than drill records formerly demonstrated I have good reasons for considerably raising my estimate, and now estimate that a yield commercially of from 45 to 55 gallons of oil per ton treated may be expected. The yield of sulphate of ammonia may be anything to or over 60lbs. per ton of shale and the wax about 60lbs. per ton. There are two corollaries still to be dealt with under by-products. The first comprehends the discovery and present development of a very valuable deposit of clay. It is fortunate for the Company that this clay exists, for we shall require very great quantities of bricks for the large works we are about to erect—works dealing with 1,000 tons of shale per day as a beginning and possibly ultimately dealing with 4,000 tons per day. The second corollary comprehends cement manufacture as an integral part of the Company's business. It is possible you will be turning out 600 tons of cement per day when your 1,000 ton shale plant is in full working order. The property you hold is capable of supplying 18 works dealing with 4,000 tons each per day for 120 years.

The resolution was carried unanimously.

San Miguel Copper Mines, Ltd.

At an extraordinary general meeting on Friday of last week, it was resolved to wind-up the company voluntarily, with Mr. E. Johnston (the secretary), as liquidator. Mr. C. A. Massauti, who presided, explained the difficulties under which the company had been carrying on its operations owing to the scarcity of freight, the great increase in working costs, and the fact that the ore mined had been steadily deteriorating in value. The consulting engineer and the manager at the mine were of opinion that the results of the investigation work in the lower levels did not warrant further outlay. The liquidator could continue to treat the heaps already there at small cost, and thus extract most of the remaining copper on remunerative terms. The machinery, rolling-stock, etc., at the mine should be easily realisable owing to the general shortage, so that, if carefully handled, the liquidation, undertaken at this stage, should produce a relatively good return to the shareholders.

Rubber Curing Patents Syndicate, Ltd.

The accounts for 1918 show a net profit, including £3,425. brought forward, of £9,626, against £4,747. The directors have carefully considered the question of the payment of a dividend, but they are unable to recommend the payment of one for the reason that patents stand in the books at £30,000., and although six years have elapsed since the syndicate was formed, no depreciation of this asset has in the past been possible. The directors recommend that £7,500. be used in the reduction of the item of patents, and the balance of £2,126 be carried forward.

DIVIDENDS.

ANGLO-CONTINENTAL GUANO WORKS COMPANY, LTD.—Interim dividend on ordinary shares at the rate of 12½ per cent. per annum (1½d. per share).

LAWES' CHEMICAL MANURE COMPANY, LTD.—Dividend for year ended June 30 of 10s. per share on ordinary and bonus of 2s. 6d. free of tax.

OUR BOOK SHELF.

MINING AND MANUFACTURE OF FERTILISING MATERIALS.—By Strauss L. Lloyd, E.M. London: Crosby Lockwood and Son; 9s. net.

A highly informative work dealing in very concise form with the raw materials, manufacturing processes, and applications of all fertilisers—phosphatic, nitrogeous, and potassic. Considerable reference is made throughout to mechanical detail, examination of commercial fertilisers, and examination of soils.

NEW COMPANIES.

Dunraven Cement and Lime Company, Ltd.—Private company. Capital £25,000., £1. shares. Office: 57, James Street, Cardiff.

Franklin Chemical Company, Ltd.—Private company. Capital £20,000., £1. shares. Manufacturers, importers, and exporters of and dealers in chemicals, etc. Solicitors: Linklater and Co., 2, Bond Court, Walbrook, E.C.

Ineson Gibbs Oil and Chemical Company, Ltd.—Private company. Capital £3,000., £1. shares. Registered office: Marshall Works, Milner Road, Selly Park, Birmingham.

J. R. Morris, Ltd.—Private company. Capital £1,000., £1. shares. Objects: To take over the business carried on at Star Works, London Street, Smethwick, as "J. R. Morris," and to carry on the business of paint and colour manufacturers and merchants, workers in ferrous and non-ferrous metals, ores, compounds and alloys, etc.

Kalchester Manufacturing Company, Ltd.—Private company. Capital £5,000., £1. shares. Manufacturing chemists, druggists, drysalts, oil and colourmen, manufacturers of and dealers in toilet requisites, etc. Registered office: 1, Williamson, Reddish, Lancs.

Masterson Roumanian Oil Syndicate, Ltd.—Private company. Capital £20,000., £1. shares. Office: 29, Great St. Helens, E.C.

Coal By-Products (Parent) Syndicate, Ltd.—Private company. Capital £5,000., £1. shares. Solicitors: Kenneth Brown and Co., Lennox House, Norfolk Street, W.C.

Kingdown (Hewas Water) Tin Mines, Ltd.—Capital £60,000., 2s. shares. Registered office: Broad Street House, E.C.

British Magnesite Calcining Company, Ltd.—Private company. Capital £100,000., £1. shares. Registered office: 14, Great George Street, S.W. 1.

Consolidated Mines of Cornwall, Ltd.—Private company. Capital £66,000., £1. shares (33,000 7 per cent. cumulative preference). Registered office: 8, Hart Street, Mark Lane, E.C.

Hovey and Lowther, Ltd.—Private company. Capital £10,000., £1. shares. Object: To take over the business of manufacturers of phosphoric acid powder, used as a substitute for cream of tartar, carried on by J. F. Lowther at the Wheelock Cream Powder Mills, Sandbach, Cheshire. Registered office: Wheelock Mills, Wheelock, near Sandbach, Cheshire.

M. H. Wilson and Sons, Ltd.—Private company. Capital £40,000., £1. shares. Object: To take over the business of chemical manure manufacturers and coal merchants carried on as "H. M. Wilson, late Wm. Wilson," at 28, Old Market and Bedford Street, Wisbech. Solicitor: A. G. Hardy, 27, Chancery Lane, W.C.

Malco, Ltd.—Private company. Capital £5,000., £1. shares. Manufacturers and merchants of cutting oils or compounds, starch substitutes, glue, size, gelatine and similar substances, etc. Registered office: 63, Norfolk Street, Sheffield.

Morgan Ebonite Company, Ltd.—Private company. Capital £30,000., £1. shares. Manufacturers of rubber, rubber substitutes and all recovered rubbers and chloride of sulphur, vulcanite, ebonite, and all chemicals used in the manufacture of indiarubber, vulcanite, and ebonite goods, etc. Registered office: Empire Works, Oldham Road, Failsworth, near Manchester.

North Cornwall Quarries Syndicate, Ltd.—Private company. Capital £20,000., in 18,000 preference shares of £1. and 40,000 deferred shares of 1s. each. Registered office: 4, Vernon Place, W.C. 1.

Products and Equipment, Ltd.—Private company. Capital £3,000., £1. shares. Manufacturers, importers, and exporters of and wholesale and retail dealers in engineering apparatus, building materials, oil, soap, grease, lubricants, agricultural produce, fertilisers, cattle feeding-stuffs, brewers' materials, and by-products. Solicitors: Holder and Wood, 6, Martin's Lane, Cannon Street, E.C.

Stockport United Chemical Company, Ltd.—Private company. Capital £25,000., £1. shares (5,000 preference). Registered office: Old Road Works, Stockport, Cheshire.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

Canada.

A correspondent in Prince Edward Island desires to obtain the address of United Kingdom exporters of superphosphate, basic slag, Paris green, arsenate of lead (powder and paste), arsenate of lime, and also potash for agricultural purposes. (Inquiry at office of High Commissioner for Canada, 19, Victoria Street, London, S.W. 1.)

Ceylon.

A firm in Ceylon wish to get into touch with (a) rubber manufacturers, with a view to representing them in Ceylon and supplying all their requirements; (b) consumers of copra and citronella oil; (c) buyers of plumbago, the firm being also large mine owners. (Reference No. 514.)

Turkey.

A firm in Constantinople, already holding important United Kingdom agencies, wish to get into touch, with a view to obtaining additional agencies, with United Kingdom manufacturers or exporters of household and toilet soap and chemicals. (Reference No. 540.)

A firm of merchants in Constantinople desire to represent United Kingdom manufacturers of paint, glass, etc., either on a commission basis or to buy for their own account. (Reference No. 541.)

Argentine Republic.

H.M. Consul-General at Buenos Aires reports that a commission agent in that city is desirous of representing United Kingdom firms for the sale of aniline dyes. (Reference No. 544.)

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Acetylene Equipment Company, Ltd. (formerly Acetylene Illuminating Company, Ltd.).—Resolved July 23, confirmed August 16: That the company be wound up. J. G. Harris, Palmerston House, Old Broad Street, E.C., chartered accountant, liquidator, who is authorised to carry into effect an agreement with the Dissolved Acetylene Company, Ltd., for the sale of the company's goodwill, undertaking, and assets at the price of £35,000., subject to such terms and conditions otherwise as he may deem advisable.

Adams (Arthur) and Co., Ltd.—Petition presented, August 19, by Bradley and Burch, Ltd., 5, Whittington Avenue, E.C. Iron, tinplate, and metal merchants. Hearing, Royal Courts of Justice, Strand, October 14. Pettiver and Parkes, 21, College Hill, E.C., solicitors.

Broughton Rubber Company, Ltd.—Claims to F. S. Burman, 29, Princess Street, Manchester, chartered accountant, liquidator, by September 30.

Manbre Saccharine Company, Ltd.—Resolved July 30, confirmed August 19: That the draft agreement submitted to the meeting and for the purpose of identification subscribed by the chairman be and the same is hereby approved, and that the company be wound up. H. P. Tongue, Fulham Palace Road, Hammersmith, secretary of the company, liquidator, who is authorised to consent to the registration of a new company. Meeting of creditors, Receiver's Office, Fulham Palace Road, Hammersmith, September 8, at 2. (Note.—The notice of the meeting is given to comply with the provisions of the Companies Acts on the voluntary winding-up of the company.)

Oowana Soap Company, Ltd., London, E.C.—J. D. Pattullo, 65, London Wall, E.C., appointed liquidator July 4.

DISSOLUTIONS OF PARTNERSHIP.

(Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.)

Mundav, J. C., and Co. (Geo. Frdk. Wm. Hussey, Frank Hewitt Warr, and Chas. Ambrose Harman), 46, 47, and 48, Orchard Lane, Southampton, oil, colour, lead, glass, and paper merchants. August 1. Debts by G. F. W. Hussey and C. A. Harman, who continue. (August 19.)

to a scrubber, where the gases are washed with heavy shale oil. The heavy shale oil is afterwards distilled, and the distillate is added to the spirit obtained in the condenser. In distilling shale, a vertical retort, fed with shale at the top and with steam at the top or lower down, is employed. About $\frac{1}{2}$ lb. of water is used for 1 lb. of shale. The shale oil is distilled at the top of the retort at about 400°C . and flows downwards with the steam, and is cracked and hydrogenated by passage over the spent shale at the bottom of the retort, which is maintained at about 600°C .

Treating Ammoniacal Liquors. D. M. Holmes, Stockton-on-Tees. British Patent, 128,401.

Ammonia is recovered from the ammoniacal liquor from plants for purifying gases from producers or the like by first concentrating the liquor, distilling with lime until a considerable proportion—for example, 75-80 per cent.—of the ammonia is recovered, and then running the liquor remaining in the still into a producer to recover the rest of the ammonia. If the producer is provided with a water lute, a solution of calcium chloride collects therein, and may be treated with nitre-cake or sodium sulphate to produce calcium sulphate and sodium chloride.

Acetone and Alcohols. A. P. H. Desborough, Royal Naval Cordite Factory, Holton Heath; J. Reilly, Parkstone; A. C. Thaysen, Parkstone; and F. R. Henley, Organford Manor, near Wareham, all in Dorset. British Patent, 128,403, of 1918.

In bacterial fermentation processes to produce acetone, together with butyl alcohol, ethyl alcohol, or other products, the yield of acetone is increased by adding, to the fermenting mass acetic acid or a soluble acetate, which becomes converted by the bacteria or their enzymes. *Granulobacter butylicum* may be used to give principally acetone and butyl alcohol. In an example, a bacterial culture is added to a cooked rice mash, and acetic acid is added at intervals during the fermentation.

Utilising Nitre-cake. J. S. Morgan, Freshfield, Lancashire. British Patent, 128,302, of 1917.

Nitre-cake is heated in a closed chamber to produce neutral sulphate, and this, while still hot, is further heated in the closed chamber with a material, such as slag, which will drive out the combined acid. The opening statement refers to the decomposition of sodium sulphate by silica or alumina. The particular process described consists in placing the nitre-cake on the surface of molten basic slag, which drives off the free acid, and then breaking the crust and stirring the residue into the body of the molten slag. This removes the combined acid and leaves the slag in a form more suitable for setts and for manure.

Acetic Anhydride and Acetyl Chloride. T. H. Durrans, Oxford; and A. Boake, Roberts and Co., Stratford, London. British Patent, 128,282, of 1917.

Acetic anhydride is prepared by mixing anhydrous acetates of the alkali or alkaline-earth metals with phosphorus and treating the mixture with chlorine, the materials being used in the proportions of 6 to 8 molecular parts of alkali acetate (or 3 to 4 of alkaline-earth acetate) to 1 atomic part of phosphorus and 3 to 5 atomic parts of chlorine; the acetic anhydride is isolated by distillation under reduced pressure or by extraction with a solvent such as carbon tetrachloride. Acetyl chloride is obtained similarly, but by using the reagents in the proportions of 3 to 4 molecular parts of alkali acetate (or $\frac{1}{2}$ to 2 molecular parts of alkaline-earth acetate) to 1 atomic part of phosphorus and 3 to 5 atomic parts of chlorine, the acetyl chloride is isolated by distillation or by extraction with a solvent such as acetylene tetrachloride.

Chlorhydrins. K. T. and H. E. Kerfoot, Bardsley, Lancashire; and J. C. Irvine and W. N. Haworth, University, St. Andrews, Fife. British Patent, 128,635.

Chlorhydrins are prepared by supplying small amounts of hypochlorous acid and ethylene or its homologues, etc., to a liquid medium, and repeating the operations until the resulting solution of chlorhydrin is sufficiently concentrated to be worked up. The process may be carried out by first passing chlorine into a copper salt solution to give a weak solution of hypochlorous acid, cutting off the chlorine supply when absorption ceases and driving off the excess chlorine from the reaction vessel by a stream of air, and thus passing ethylene into the solution; the operations are repeated until the solu-

tion contains, say, 40 grammes of chlorhydrin per litre. Stronger solutions may be obtained by periodically neutralising the hydrochloric acid formed—e.g., by means of basic copper carbonate—and continuing the operations. The chlorhydrin is then separated by fractional distillation or by extraction with ether, etc. During fractional distillation of the aqueous solutions, calcium carbonate may be added to neutralise hydrochloric acid. The product is finally purified by fractional distillation, washing with petroleum spirit, and drying. Ethylene dichloride is formed as a by-product in the process. The process may be carried out on the large scale in packed towers through which the liquid circulates and comes into contact alternately with chlorine and ethylene, or in a tower divided by a series of shelves into zones containing alternately chlorine and ethylene, through which the liquid flows.

Treatment of Wool-scouring Liquors. W. P. Thompson, Liverpool. (A communication from F. E. Underwood and B. F. Illston, New York.) British Patent, 128,730, of 1918.

Wool-scouring and like liquors are treated to recover fats and sodium and potassium salts by heating under pressure with an alkaline-earth salt such as magnesium sulphate. The liquor from a scouring-bowl 1 is passed to a settling-tank 3, and thence to an autoclave 7, in which it is heated with magnesium sulphate to about 350°F . under a pressure of about 125 lb. per sq. in. The mixture is passed to a settling-tank

11, from which the supernatant liquor is run through a centrifugal 13 to a storage tank 15. The liquor is evaporated to recover sodium, potassium, and nitrogen compounds. The sediment from tank 11 is passed to a storage tank 17, and thence to a steam-jacketed kettle 19, in which it is treated with sulphuric acid. The treated liquor is cooled in tank 21. Fatty matters are separated by filtration or by a centrifugal 23. The clear liquor containing magnesium sulphate is passed to a storage tank 25, and is evaporated to obtain the salt for use again.

Plastic Compositions. G. L. Scott, London. British Patent, 128,477, of 1918.

Lime is used in admixture with phenol-formaldehyde resins to form plastic compositions. Filling components of the mixtures are fuller's earth, steatite, China-clays, clays, wood flour meal and pulp, waste cotton material, jute, and other fibres. Indiarubber, gutta-percha, or the like may be incorporated with the resin before addition of the calcium oxide and filling material. The mixture is moulded, dried at about 75 to 80°F ., and heated to 350 to 400°F . In an example, from 5 to 10 per cent. of rubber dissolved in naphtha is added to an alcoholic solution of a synthetic resin, and then, after stirring, 5 to 20 per cent. of the powdered calcium oxide, the fillers, if used, being afterwards stirred in gradually.

Alkali Cyanides. W. J. Mellersh-Jackson, London. (A communication from the Air Reduction Company, New York.) British Patent, 128,507, of 1919.

The extraction of cyanide from a furnace product obtained by nitrogenising a mixture of alkali carbonate and carbon, with or without a catalyst—for instance, a mixture of sodium carbonate, coke, and iron or iron oxide—is effected by a composite solvent consisting of a mixture of water with an organic solvent miscible therewith, such as methyl or ethyl alcohol or acetone. Any alkali oxide or hydroxide in the furnace product may be removed by treatment of the wetted product with carbonic acid or by passing carbonic acid through the solution before or after it is separated from the residue. The residue, with suitable additions to make up its composition, may be used again.

Acetone, Alcohols, Etc. A. P. H. Desborough, Holton Heath; J. Reilly, Parkstone; A. C. Thaysen, Parkstone; and F. R. Henley, Organford Manor, near Wareham, Dorset. British Patent, 128,714, of 1918.

In bacterial fermentation processes for the production of acetone, alcohols, etc., one or more volatile fatty acids (acetic, propionic, etc.) or their salts are added to the mash, whereby the total production of volatile products is increased or modified. According to an example, propionic acid is added at intervals to a maize mash undergoing fermentation by the "*n*-butyl alcohol-acetone" producing organism; the products obtained consist of acetone, butyl, and propyl alcohols, and a little ethyl alcohol.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Aminobenzoic Ester Derivatives. Soc Chimique des Usines du Rhone Anciennement Gilliard, P. Monnet, et Cartier, Paris. British Patents, 128,552, 128,553, and 128,554. Convention date, June 20, 1918.

Mono- and di- β -oxyethylaminobenzoic esters of the formulæ $\text{HO.CH}_2\text{CH}_2\text{NHC}_6\text{H}_4\text{COOR}$ and $(\text{HO.CH}_2\text{CH}_2)_2\text{N.C}_6\text{H}_4\text{COOR}$ (R = alkyl), are prepared by heating aminobenzoic esters with one or two molecular parts of ethylene oxide at $50\text{--}110^\circ\text{C}$; the reaction may be accelerated by adding small amounts of water or alcohol. Examples are given of the preparation of ethyl esters.

β -halogenethylaminobenzoic esters of the formula $\text{X.CH}_2\text{CH}_2\text{NHC}_6\text{H}_4\text{COOR}$ (X = halogen, R = alkyl) are prepared by treating the corresponding β -oxyethylaminobenzoic esters with halogenating agents, such as phosphorus or sulphur halides or thionyl chloride or bromide. Examples are given of the preparation of β -chloroethyl-*p*-aminobenzoic ethyl ester.

β -alkylaminoethylaminobenzoic esters of the formula $\text{R}^1\text{N.CH}_2\text{CH}_2\text{NHC}_6\text{H}_4\text{COOR}$ (R^1 = hydrogen or alkyl, R = alkyl) are prepared by heating the corresponding β -halogenethylaminobenzoic esters with alkylamines under pressure. An example is given of the preparation of diethylaminoethyl-*p*-aminobenzoic ethyl ester.

Electrolytic Chlorine. P. L. Hulin, Grenoble, France. British Patent, 126,992. Convention date, July 17, 1915.

Chlorine is separated from gaseous mixtures by absorption in a solution of a lower chloride such as ferrous chloride, or cuprous chloride, or a mixture of such chlorides, and by electrolysis the product, acidified by hydrochloric acid, to regenerate pure chlorine and the lower chloride for re-use. The chlorine obtained may be liquefied. The original gaseous mixture may be that obtained by the Deacon process, or by the electrolysis of fused chlorides of alkali and alkaline-earth metals. In the latter case it may be scrubbed with water to remove fumes, mainly chlorides, and then passed up one or more earthenware towers down which flows the absorbent solution. Each electrolytic cell, which may be of earthenware, is provided with a very porous partition, such as a sheet of asbestos, through which the solution passes from anode to cathode, overflowing from the cathode compartment. An electric pressure of about 2.5 volts per cell is employed. The initial absorbent solution may contain 30 per cent. of ferrous chloride, but after complete conversion to ferric chloride, only a part, say a third, of this salt is reduced by electrolysis, in order to avoid the production of iron and hydrogen.

Catalytic Production of Ammonia. Nitrogen Corporation, Providence, Rhode Island, U.S.A. British Patent, 128,939. Convention date, June 25, 1918.

Ammonia is produced from its elements at comparatively low temperatures and under pressure by a nitrogenous catalyst, which may contain carbon, and which is employed under sufficient pressure to prevent the dissociation or decomposition of the catalyst during the process, but not under a pressure greatly exceeding this. The catalysts mentioned are the cyanamides of calcium, barium, strontium, copper, and silver, the nitrides of copper and silver, and paracyanogen. The catalysts should be prepared under a lower temperature and pressure than those used in the catalytic synthesis, and should be in a porous condition. Calcium cyanamide in suitable form is obtained by dissolving the commercial body in water, removing sulphur by silver nitrate, passing carbonic

acid through the filtered solution to produce free cyanamide, dissolving the crystallised free cyanamide in liquid ammonia, and adding metallic calcium; or hydrocyanic acid gas may be passed through a solution of calcium in liquid ammonia, forming calcium cyanide, which on heating in the catalytic apparatus in the nitrogen-hydrogen mixture blackens, and is apparently converted into calcium cyanide. Barium and strontium cyanamide are prepared by heating the pure cyanide in nitrogen or ammonia at about $350\text{--}400^\circ\text{C}$. Copper and silver cyanamides are prepared by reacting with cupric or silver chloride on a pure solution of calcium cyanamide, the precipitated product being carefully dried in small portions; or by preparing ammonium cyanamide by adding ammonium carbonate or oxalate to a solution of calcium cyanamide, filtering, and adding copper or silver chloride. Copper and silver cyanamides are converted into the nitrides, which are also catalysts, by heating to about 500°C . in nitrogen and hydrogen when hydrocyanic acid is evolved. Copper or silver cyanamide prepared as described above may be treated with a solution of calcium in liquid ammonia, and the ammonia expelled, the product being then heated to about $250\text{--}300^\circ\text{C}$, when a mixture of copper or silver and calcium cyanamides with free copper or silver is produced. Dry silver cyanide is heated to $200\text{--}300^\circ\text{C}$ to form a mixture of silver and paracyanogen. Paracyanogen may be used when otherwise prepared. Paracyanogen may be dissolved in sulphuric acid and introduced into pumice or other support, after which the support is treated with water to precipitate the paracyanogen and wash away the acid.

Ammonium and Sodium Sulphates. Soc. Industrielle de Produits Chimiques, Paris. British Patent, 128,895. Convention date, June 22, 1918.

The process described in the parent specification for treating the double salt $(\text{NH}_4)_2\text{SO}_4.\text{Na}_2\text{SO}_4.4\text{H}_2\text{O}$ prepared by the action of ammonia on sodium bisulphate by heating it with water to about 110°C . to separate anhydrous sodium sulphate, and, after filtering, cooling the mother liquor to separate ammonium sulphate, is carried out in the apparatus illustrated. A charge of the double salt, water, and a small quantity of ammonium sulphate is introduced into the vessel A, and is heated by a steam coil and agitated. When a temperature of $110\text{--}111^\circ$ is reached, the contents are passed into a filter B heated by a steam jacket. The mother liquor is passed into a vessel E, and is cooled to 62°C . Ammonium sulphate together with a small quantity of sodium sulphate crystallises and is separated in a filter F. The mother liquor is concentrated in an apparatus I, and is returned to the vessel A together with a quantity of the double salt and a small quantity of sodium sulphate sufficient to obtain a charge of the original composition. The sodium sulphate in the filter B is washed with a nearly boiling and saturated solution of sodium sulphate from a reservoir C. The wash-water passes either into the vessel E or into a reservoir D. The ammonium sulphate in filter F is washed with a solution of ammonia sulphate saturated at 60°C . The wash-water passes either into apparatus I or to a reservoir H.

Recovering Phenols. M. E. L. Ponchon, Ban-Saint-Martin, Lorraine. British Patent, 126,965. Convention date, May 10, 1918.

Phenol and its homologues, such as cresols, are recovered from gases, in which they occur in a gaseous or atomised state, by washing the gases with mineral, vegetable, or animal oils. The resulting solution is treated with a current of hot air, gas, or steam of $100\text{--}150^\circ\text{C}$, and the vapours of phenol, etc., so obtained are condensed and decanted if necessary. The process is applicable to the recovery of phenols that have been taken up in the separation of ether, alcohol, acetone, etc., from gases by washing with phenols.

FARADAY SOCIETY.—The offices of the Faraday Society have been removed from 82, Victoria Street, S.W., to 10, Essex Street, Strand, W.C.2. Mr. F. S. Spiers, B.Sc., remains secretary of the society.

PETROLEUM TECHNOLOGY.—A Department of Petroleum Technology, under Professor P. G. H. Boswell, has been instituted at the Liverpool University, the studies beginning with the next session.

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London 90%, 1s. 10d. to 2s.; North, 1s. 8d. to 1s. 9d.; 50%, 1s. 10d.; North, 1s. 8d. to 1s. 9d. naked. Carbollic acid, crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 9d. to 9½d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch 72s. 6d. to 75s.; East Coast, 67s. 6d. to 72s. 6d. f.o.b.; West Coast, 55s. to 57s. 6d., f.a.s. Solvent naphtha, naked, London, 90-100%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-100%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthaline, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 6d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid, 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b., other ports. Sulphate of ammonia; home trade, £19. 10s. per ton; basis 24½%. Nitrate of soda, £21. to £22.

FERTILISER MATERIALS.

LIVERPOOL, THURSDAY.

Nitrate of soda continues firm, the quotations on spot for 95-96% quality being £20. 2s. 6d. per ton, net cash, f.o.r., prompt delivery. East Indian bone meal is easier, and the nearest value is now £14. 5s. per ton, net cash, ex ship, Liverpool, for September-November shipment. On spot, holders require £15. per ton, net cash, for 41% and 45% quality. Mineral phosphates are without alteration, and values at present are only nominal. Dried blood is rather irregular, the nearest value being about 30s. per unit of ammonia per ton.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £101. 10s. to £101. 15s. cash; £102. 10s. to £102. 15s., three months; electrolytic, £110. to £120. Tin: Standard, £278. 10s. to £279.; cash, £272. 10s. to £273., three months; Straits, £279. 10s.; English, £276. to £277. Lead: Soft foreign, £24. 15s.; English, £26. Spelter, £41.; hard, £30. to £32. Antimony, English regulus, 90%, £42. Aluminium, £150.; Nickel, £205. delivered, packages extra. Quicksilver, £23. 10s. to £24. Bismuth, 12s. 6d. Platinum, 442s. per oz. Wolfram, 30s. per unit.

SWANSEA MARKET REPORT.

THURSDAY.

Tinplate prices very firm at 36s. per box for standard sizes f.o.b. Copper maintains good inquiry at £100. 15s. per ton for prompt delivery and £101. 10s., three months. Tin firm at £275. 10s. cash and £268. 15s., three months. Lead steady with small business at £24. 17s. 6d. per ton for Spanish and £26. for English. Spelter firmer at £39. 15s. per ton prompt and an additional £1. for over November. Zinc sheets showed activity at £65. per ton f.o.b., at New York, with English at £64. 10s. Silver, 59d. per ounce. Quicksilver, £23. 10s. per bottle. Nickel, £205. per ton, including delivery London or equal. Aluminium, £150. Antimony remains nominal with English regulus 90% at £42. Sulphate of copper dull at £43. per ton. Sulphate of ammonia steady with delivery present month at £19. 10s. per ton. Nitrate of soda quiet and steady at 21s. 9d. per cwt. in bags. Seed oils quiet with scarcity of offers. Palm oil very firm with good inquiry. Lagos £92. 5s.; softs £92.; Benin £86. 10s.; and hards £84. per ton. Turpentine firm at £6. 11s. per cwt. Rape oil quiet at £5. 12s. per cwt. in casks. Arsenic very quiet with firm quotations round £50. per ton for white powdered in bags. f.o.b. Oxalic acid quiet at 1s. 2½d. per bottle. Pitch dear and scarce at 55s. per ton, ex ship.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

Business continues brisk in nearly all branches of the trade, and values generally are well maintained. Small resale lots of 70% caustic soda are still available at £17., and refined bicarbonate of soda, bags, at £7. 10s. per ton, 58%. Alkali

is quiet at £6. 15s., ex store. Bleaching powder quiet at £15., softwoods, on rails; and £14. hardwoods, f.o.b. Chlorate of soda easy at 6½d. per lb. Potash 1s. per lb. Roasted saltcake, in bulk, firm at 60s. per ton, carriage paid. Borax is scarce, and high prices are asked for spot parcels. Recovered rock sulphur unchanged at £17., on rails. Sulphate of copper is still neglected for export, and price is only nominal at £43. per ton, f.o.b. Nitrite of soda is firm on the spot at £60., basis 100%, but parcels are offered much cheaper to arrive. Commercial hyposulphite of soda steady at £16. 10s. per ton. Phosphate of soda a shade dearer at £27. per ton. White powdered arsenic continues scarce, and spot lots of Cornish are realising £60. per ton. Yellow prussiate of potash is unaltered at 1s. 9d. per lb. Soda higher on the week at 7½d. per lb. Lead salts continue in steady request. White acetate at £81., brown £70., and nitrate £56. per ton. Acetate of soda only moving slowly at £52. per ton. Acetic acid unchanged. English brown acetate of lime firmly held for £11. per ton. Grey easy at £17. per ton. Demand for miscible and solvent wood naphtha is dull. Trade in green copperas is still on the quiet side, and stocks are increasing. Oxalic acid unaltered at 1s. 2½d. per lb.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

Inquiries for the heavier chemicals have come in rather freely, and have seemed to indicate the existence of a more settled feeling in the principal fields of consumption in the Northern counties. A very fair demand has again been experienced on export account. More inquiries have come to hand from European countries, and have helped to give a brighter aspect to the market. Bleaching powder has been more in request. Quotations are still £14. 10s. to £15. per ton free on rail or conveyance, in buyers' packages, and £17. per ton for export. Chloride of calcium has been in fair inquiry, and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has been well inquired for, and is £24. per ton for 76%; £22. per ton, for 70 to 72%; and £19. per ton for 60 to 62%. Nitrate of soda has been in moderate demand, and is £20. 10s. to £21. 10s. per ton. Saltcake has sold more freely, and is £6. 10s. per ton in casks, f.o.b. Soda crystals have been in good request and are £5. per ton in 2cwt. bags f.o.r. at works. Bicarbonate of soda has been steadily inquired for and is £7. 5s. to £10. per ton, according to terms of delivery. Borax has again been in rather active demand, and scarce for early deliveries. It is £42. per ton for ordinary, and £44. per ton for powdered, in bags. Ammonia alkali has had a brisk inquiry and is £6. to £6. 5s. per ton, f.o.r. at works. Hypo-sulphite has been in fair request, and is £17. per ton for ordinary and £22. per ton for pea crystals. Sulphite of sodium has been but little called for and is £10. per ton for ordinary and £16. to £18. per ton for pea crystals in lewt. kegs. Bichromate of soda has been rather more in request and is 9d. per lb. Phosphate of soda has been in moderate demand, and is £25. per ton. Sulphide of sodium has been in somewhat better request, and is £20. per ton in casks and £22. per ton, in drums. Chlorate of potash has been quieter, and is 1s. 1d. to 1s. 3d. per lb. Permanganate of potash has sold more readily and is 3s. 3d. to 3s. 6d. per lb. Sulphate of potash has been little in request and is £40. per ton. Carbonate of potash has been in moderately active inquiry, and is £90. to £95. per ton for 80 to 85%. Caustic potash has sold with some freedom, and is £110. to £120. per ton. Nitrate of potash has been in very fair request, and is £55. to £60. per ton for refined and £40. per ton for ordinary. Canadian potashes have again been very quiet. Montreal, first quality are £210. to £220. per ton, and second quality, £190. to £210. per ton. Bichromate of potash has had a fair inquiry and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been quiet and is 1s. 9d. to 1s. 10d. per lb. Sulphate of ammonia has been more inquired for and is £80. per ton for lump, £75. per ton for seconds, and £5. per ton extra for ground. Sulphate of ammonia has had a quietly steady sale and is £19. 10s. per ton, less traders' discount of 10s. per ton, free to nearest wharf or station;

to September 30. Prices for later dates have been fixed as follows:—October: £20. 10s. per ton; November, £20. 15s.; December, £21.; January, 1920, £21. 7s. 6d.; February, £21. 15s.; March and April, £22. per ton. Carbonate of ammonia has been rather more in request, and is 6½d. per lb. Muriate has been very quiet and is £50. to £60. per ton, according to quality. Magnesia has again been in very fair demand. Carbonate is £3. per cwt., and sulphate, £10. to £16. per ton, according to grade. Alum has been in good request, and is still in very limited supply for early deliveries. For the home trade, £18. 10s. per ton is still being asked, and, for export £18. 10s. to £19. 10s. per ton. Aluminoferric has been neglected, and is £8. 10s. to £12. per ton, according to quality. Sulphate of alumina has been rather more inquired for, and is £12. to £17. per ton, according to grade. Sulphur has been in fairly active demand. English kinds are: flowers, £32. per ton; roll, £28. per ton, and rock, £22. per ton, in bags, f.o.r. Sicilian grades are: flowers, £28. per ton; roll, £22. 10s. per ton; and rock, £17. 15s. per ton. Cream of tartar has been in very fair request and is £11. 10s. to £11. 15s. per cwt. Tartaric acid has been quieter, and is 3s. 1d. to 3s. 3d. per lb. Boracic acid has been in good request and is £72. per ton for crystals and £74. per ton for powdered. Oxalic acid has been in quietly steady request and is 1s. 3d. per lb. Citric acid has met with a fair inquiry and is 4s. 4d. per lb. White acetate of lead has been very quiet and is £85. to £90. per ton. Arsenic has been but little in request and the price is higher. It may be given as £55. per ton for white powdered. Sulphate of copper has again been very quiet and is £44. per ton, for agricultural purposes in the United Kingdom, and £43. per ton, less 5%, in casks, f.o.b. at Liverpool.

TYNE CHEMICAL REPORT.**TUESDAY.**

Trade continues very steady, with an increasing demand for caustic soda and bleaching powder for home markets. Prices show very little fluctuation. The inquiry for export is also showing signs of improvement. The following prices are per ton, net: Bleaching powder, softs and hards, £15.; caustic soda, 74-77%, £23. 5s.; do., 70%, £22.; do., 60%, £20.; recovered sulphur, 2cwt. bags, £24.; hyposulphite of soda, 5-7cwt. casks, £19.; 1cwt. kegs, £25.; sulphite of soda, 5-7cwt. casks, £12.; do., 1cwt. kegs, £20.; silicate of soda, 75° Tw., £9. 12s. 6d.; do., 100° Tw., £10.; do., 140° Tw., £10. 10s.; soda crystals, 2cwt. bags, £5.; sulphate of soda (saltcake), in bulk, £3. 10s.; pure white sulphate of alumina, 14-15%, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18.; do., refined concentrated solid, 60-62%, £25.; hydrate of barium, crystals, £56.

COALS.—Market continues very strong, and collieries are well booked up for September. The home demand and official requisition leave very limited quantities for oversea trade.

To-day's quotations: Best Northumbrian steam, 95s. to 100s. per ton; second qualities, 80s. to 90s.; Northumberland small coals, 75s. to 80s.; seconds, 70s.; best Durham steam coals, 90s. to 100s.; seconds, 80s. to 85s.; Durham gas coals, 80s. to 85s.; seconds, 65s. to 75s.; Durham bunkers, 70s. to 80s.; foundry coke, 85s. to 90s.; gas coke, 85s. to 90s.

WEST OF SCOTLAND CHEMICALS.**GLASGOW, Wednesday.**

During the past week there has been fairly good inquiry for all the different kinds of chemicals, and it is reported that a number of pretty big deals have been carried out. There are no changes worth recording in the general market conditions, and as far as prices are concerned, these are maintained at a steady level and without quotable variations on the previous range. Altogether the feeling of the market may be described as firm and steady, and with business on the upward grade. Current quotations: Arsenic, £55. per ton, net, Glasgow; bicarbonate of soda, £8. 15s. and £10. per ton for 6-8 casks and 1cwt. kegs, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags, and borax crystals, £39. for 2cwt. bags, carriage paid; caustic soda, white, 70-72%, £24. per ton, net, Glasgow; chlorate of potash, 1s. 1d. per lb. net, Glasgow; chlorate of soda, £3. 4s. per cwt. net, Glasgow; citric acid, 4s. 4d. per lb. 5% Glasgow; cream of tartar 98% £11. 5s. per cwt. net, Glasgow; paraffin wax, U.K. deliveries 125°, 6½d. to 6¼d.; 121-3°, 5½d. to 5¼d.; 118-20°, 5¼d.; 110-12°, 4d. to 4¼d.; and 98-102°, 4d. to 4¼d.; salammonic, £80. and £75. per ton, net, any port, for first and second lump respectively; salammonic crystals, £85. per ton, net, Glasgow; salepetre, £3. 4s. net, Glasgow; tartaric acid, 3s. 1d. per lb., 5% Glasgow.

Among the sea oils, quantities of all the different varieties have once again been available, although in some cases not sufficiently so to supply the demand. Whale oils have been more in the forefront, with the pale, brown, and black all on offer, but yellow has still been an absentee. Pale has been selling at 102s., brown at 76s., while black has gone down in value from 78s. to its present quotation of 74s. Newfoundland cod has also again come on offer at 79s., while a noticeable change in market conditions has been that both pale seal and Menhaden have again been purchasable, the former at 96s. and the latter at 86s. Quality generally is satisfactory, and demand all round is fairly steady.

In the Scottish coal trade outputs are still poor, and demands for all purposes very strong, with the result that the collieries are far behind with their orders, and all classes of material are extremely scarce. For local requirements there is no easing-off in the demands, and consequently the greater portion of the outputs is being taken up to fulfil these requirements. In the export branch of the trade, only very limited quantities are being exported.

1 t. 4 c., £52.

AMMONIUM NITRATE

Antwerp, 25 t. 1 c., £880.

AMMONIUM PHOSPHATE

Bordeaux, 2 t. 10 c., £85.

AMMONIUM SULPHATE

Dunkirk, 309 t. 1 c., £6,805.

AMYL ACETATE

Buenos Ayres, 1 cs., £7.; Rotter-
dam, 6 drms., £560.

ANTIMONY

Novorossisk, 1 t.

ANTIMONY REGULUS

Amsterdam, 10 t.; Antwerp,
5 t. 10 c.

ANTIMONY SALTS

Amsterdam (F.), 1 brl., £92.

ANTIMONY SULPHIDE

Antwerp, 6 cks., £255.; Dunkirk,
3 cks., £61.; Naples, 6 cks., £90.;
Valparaiso, 2 cks., £43.; Yoko-
hama, 14 cks., £459.

ARSENIC

Penang, 4 c., £9.; Piraeus, 12 c.,
£51.; Rangoon, 1 c., £8.;
Salonika, 4 c., £11.; Sao Paulo,
5 t. 17 c., £312.; Valencia, 2 t.,
£70.

BARIUM BINOXIDE

Melbourne, 40 drms., £600.

BEES WAX

Amsterdam, 6 t. 17 c.

BENZALDEHYDE

Barcelona, 1 cs., £22.

BENZOIC ACID

Calcutta, 2 cks. (pt.), £36.;
Melbourne, 1 ck. (pt.), £8.

BENZYL CHLORIDE

Rotterdam, 1 ck., £11.

BISMUTH CARBONATE

Buenos Ayres, 1 cs. (pt.), £11.;
Durban, 1 cs. (pt.), £32.

BISMUTH SALICYLATE

Bilbao, 1 cs. (pt.), £8.; Buenos
Ayres, 1 cs. (pt.), £20.; Calcutta,
1 cs. (pt.), £38.

BISMUTH SUBNITRATE

Monte Video, 1 cs. (pt.), £10.

BORAX

Amsterdam, 4 t. 19 c., £190.;
Delagoa Bay, 2 c., £9.; Madras,
2 t. 10 c., £98.; Ostend, 9 t. 17 c.,
£384.; Rangoon, 2 c., £6.;

BORIC ACID

Cape Town, 1 c., £5.; Cartagena
Col., 1 c., £7.; Constantinople,
3 c., £15.; Durban, 2 c., £11.;
Hasingen, 6 c., £33.; Paris, 5 t.,
£370.; Piraeus, 2 c., £11.;
Shanghai, 20 t., £1,480.

CABLE WAX

Antwerp, 3 t. 4 c.

CALCIUM CARBONATE

Cape Town, 9 t. 16 c., £244.;
Pt. Elizabeth, 4 t. 18 c., £121.

CALCIUM CHLORIDE

Alexandria, 2 cs., £11.

CALCIUM GLYCEROPHOSPHATE

Christiania, 1 cs. (pt.), £31.

CALCIUM HYPOPHOSPHITE

Genoa, 5 cs. (pt.), £45.

CALCIUM LACTATE

Lisbon, 1 cs. (pt.), £5.

CARBON BISULPHIDE

Antwerp, 10 cs., £40.; Sydney,
20 cks., £59.

CARBON TETRACHLORIDE

Antwerp, 2 drms., £15.

CARNAUBA WAX

Amsterdam, 1 t. 1 c.; Genoa,
1 t. 1 c.

CAUSTIC POTASH

Bombay, 1 cs. (pt.), £14.;
Rangoon, 1 cs., £14.

CERESINE WAX

Abo, 1 t.; Antwerp, 24 t. 5 c.;
Amsterdam, 4 c.; Bordeaux, 6 c.;
Paris, 5 c.; Rotterdam, 61 t.

£14.; Sydney, 11 c., £21.;
Wellington, 1 t., £38.

MANGANESE Binoxide

Antwerp, 3 cks., £31.

MANGANESE RESINATE

Brussels, 3 brls., £32.

MERCURY CHLORIDE

Bilbao, 1 cs. (pt.), £16.; New
York, 10 cs., £202.

MERCURY OXIDE

Lisbon, 1 cs. (pt.), £14.

MERCURY OXIDE & CYANIDE

Amsterdam, 1 cs., £51.

METHYL SALICYLATE

Antwerp, 2 drms., £44.; Bou-
logne, 5 cs., £58.; Genoa, 4
drms., £100.; Italy, 10 drms.,
£90.

MINERAL WHITE

Amsterdam, 25 t.

NICKEL SALTS

Amsterdam, 2 cs., £26.; Yoko-
hama, 20 cs., £55.

NICKEL SULPHATE

Paris, 48 cks., £525.

NITRIC ACID

Penang, 1 c., £6.; Teluk Anson,
1 c., £14.

OXALIC ACID

Genoa, 3 cks., £142.; Melbourne,
1 brl., £15.

PARAFFIN WAX

Antwerp, 2 t. 3 c.; Bordeaux,
4 t. 10 c.; Genoa, 10 t. 11 c.;
Gothenburg, 10 c.; Lisbon, 2 t.
10 c.; Paris, 18 c.

PHOSPHORIC ACID

Genoa, 14 crbys., £192.

PHOSPHORUS

Sydney, 10 cs., £130.

PHOSPHORUS (AMORPHOUS)

Bombay, 2 cs., £30.

PHOSPHORUS SESQUISULPHIDE

Alicante, 45 cs., £724.

PLUMBAGO

Buenos Ayres, 2 t. 19 c.; Durban,
3 t.; Helsingfors, 1 t. 10 c.;
Penang, 4 c.

POTASSIUM BROMIDE—
Calcutta, 2 cks., £55.; Dunkirk (F.), 4 cs., £63.; Melbourne (F.), 1 kg., £14.

POTASSIUM CARBONATE—
Dunkirk (F.), 2 t. 6 c., £355.; Lisbon, 1 cs., £5.; Rangoon, 1 ck., £21.

POTASSIUM CHLORIDE—
Barcelona, 1 c., £15.; Sydney, 10 t., £54.

POTASSIUM CITRATE—
Calcutta, 2 ck., £87.

POTASSIUM CYANIDE—
Karachi, 1 cs. (pt.), £11.; Oporto, 1 cs., £13.

POTASSIUM FERROCYANIDE—
Bilbao, 1 kg., £17.

POTASSIUM HYDROXIDE—
Rangoon, 2 cs., £46.

POTASSIUM HYPOPHOSPHITE—
Genoa, 5 cs. (pt.), £45.

POTASSIUM IODIDE—
Calcutta, 1 cs. (pt.), £77.; Rotterdam, 6 cs., £440.; Swatow, 1 cs. (pt.), £6.; Tientsin, 5 cs. (pt.), £9.

POTASSIUM PERMANGANATE—
Durban (F.), 3 cs. (pt.), £6.

POTASSIUM PRUSSATE—
Melbourne, 3 kgs., £32.

POTASSIUM SULPHATE—
Sydney, 1 cs., £14.

POTASSIUM SULPHIDE—
Lisbon, 1 cs. (pt.), £5.

POTASSIUM SULPHITE—
Cape Town, 1 kg., £5.; Montreal, 14 pkgs., £47.

POTASSIUM SULPHOGUAIACOLATE—
Malaga (F.), 1 cs. (pt.), £23.

QUININE—
Calcutta, 5,500 ozs.; Cape Town, 190 ozs.; Palermo, 10,000.

ROSIN—
Genoa, £32.

SALICYLIC ACID—
Calcutta, 3 cs., £14.; Genoa, 40 kgs., £150.; Oporto, 1 cs., £6.; Singapore, 1 cte., £9.

SALT—
Antwerp, 1 t.; Bombay, 5 t.

PRICES CURRENT.

THURSDAY, Sept. 4, 1919.

PREPARED BY MESSRS. HIGGINBOTTOM AND CO., 21, SPRING GARDENS, MANCHESTER.

The values stated are F.O.R. at makers' works, or at usual ports of shipment in U.K., unless otherwise specified
The prices in different localities may vary.

Acids:—			£ s. d.	
*Acetic 40% and 60%	... per cwt.	30/- & 45/-		
* " Glacial	... per ton	85 0 0		
Arsenic, S.G. 2,000°	... per ton	70 0 0		
Boric Crystals	... "	72 0 0		
*Fluoric	... per lb.	0 0 7		
*Muriatic (Tower Salts), 28° Tw.	... per carboy	0 6 6		
*Nitric, 80° Tw.	... per ton	32 0 0		
Oxalic	... per lb.	0 1 2½		
Phosphoric, 1,750°	... "	0 1 9		
*Sulphuric (fuming, 70%)	... per ton	—		
* " (Pyrites, 168°)	... "	7 18 9		
* " (" 140°)	... "	4 10 0		
* " (free from arsenic, 144°)	... "	5 7 4		
Tannic (commercial)	... per lb.	0 2 6		
Tartaric (crystals)	... "	0 3 1		
*Acetone	... per ton	80 0 0		
*Alum, loose lump (delivered)	... "	17 0 0		
Alumina Sulphate (pure)	... "	17 0 0		
Aluminoferrous (in slabs)	... "	8 10 0		
Aluminium (Ingot Metal, 98/99%)	... per ton	150 0 0		
*Ammonia, Anhydrous	... per lb.	0 1 10		
* " 880	... per ton	33 0 0		
* " 920	... "	20 0 0		
" Carbonate	... per lb.	0 0 6½		
" Muriate (grey)	... per ton	47 0 0		
" (salammoniac) 1st & 2nd, per cwt.	80/- & 75/-			
" Nitrate	... per ton	60 0 0		
" Phosphate	... "	110 0 0		
" Sulphate (grey), London, net	... "	—		
" " Itall	... "	—		
" " Manchester	... "	—		
*Aniline Oil (pure)	... per lb.	0 1 2		
Aniline Salt	... "	0 1 2

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows :—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers) ...	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are :—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are :—

London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barten House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

EDITORIAL NOTICES.

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than Wednesday morning.

Readers are invited to forward items of intelligence, company reports and balance-sheets, or cuttings from local newspapers of interest to the trades concerned.

CURRENT TOPICS.

THE BRITISH ASSOCIATION.

AFTER an interval of three years the meetings of the British Association have been resumed, and a gap which their discontinuance caused in the scientific life of the country has been filled. The contributions to the Association have always been marked by great interest and a very high standard of scientific attainment, and this year's addresses in no way fall behind. It is deeply to be deplored that so many of our great men who in the past have contributed so largely to British science have joined the great majority since the last meeting at Newcastle.

It is to be hoped that the admirable address by its distinguished President will be largely read and studied, as it will bring home the extraordinary scientific developments that have marked the years of war. It may seem regrettable that the pressure of war was needed to produce these great achievements, but in our opinion the fact to be emphasised is that the ability to do what was done was all the time latent among our scientific and technical men. Once this fact is realised by our governing classes there should be no limit to the future possibilities of this Empire. Words of warning, however, were delivered both by Professor Bedson in his presidential address to the Chemical Section, and by Sir W. Pope, that the lessons of the war have not yet been grasped, and that there is great danger of our falling back into that state of unpreparedness that was nearly our undoing.

Sir W. Pope also pointed out the fundamental difference between our own war factories and those of Germany. The latter were built, in great part, during peace, but with the possibility of their use in war ever before them, and were paid for as the result of successful pre-war trading. Our own factories, being purely a war product, cannot readily be turned to peaceful uses, and must be regarded more or less as a dead loss. Or, to use Sir W. Pope's words, we have paid for the German factories as well as for Gretna.

In conclusion, we should like to refer briefly to Sir Charles Parsons' affirmation that unless this country can find new sources of energy, it must decline from its present high estate. It was suggested that the heat

of the earth could in some way be utilised, and that a shaft twelve miles deep should be sunk to investigate the interior. There is undoubtedly an incalculable store of energy here, and there does not appear to be any inherent obstacle in the way of making such a supply available. That our coal supply will one day be exhausted is certain, and civilisation must come to an end if there is nothing to take its place.

TRADE RETURNS.

If it be possible to glean any scraps of comfort from the monthly Board of Trade returns, we think it is our duty to do so. Although it must necessarily be a very long time before we can regard the figures with any degree of complacency, yet in the returns just published there are symptoms which can be considered hopeful. One feature of good augury is that the rise in imports, generally speaking, is no longer so much a matter of values, but that we are getting greater value for our money than has been the case for so long a time. The August figures show an increase of 32½ per cent. in the tonnage entered with cargoes, the increase in values being 35 per cent. This is a good approximation, and it is to be hoped the trend will continue in the same direction. Then again, although the disparity between what comes in and has to be paid, and what goes out as a partial offset, is still enormous, the gap has been somewhat lessened. The actual figures are:—Total imports, £148,832,393., total exports £90,084,522., giving an adverse balance of over £58,000,000. The corresponding figures for 1918 showed an adverse balance of nearly £65,000,000., but the value of the exports for August, 1919, was nearly twice that for the corresponding month in 1918.

Dealing with the chemical trade in particular, we find much greater relative changes than are indicated by the total returns. For instance, the value of the imports has fallen from £4,224,882. in August, 1918, to £1,773,344. last month, or a decrease of no less than £2,451,538., or nearly 60 per cent. The fall has chiefly occurred in the unenumerated list (including acetate of lime, acetone, muriate of ammonia, and sulphuric acid), and consequently may be regarded as due to the cessation of the war. No carbide of calcium was imported, and brimstone, glycerine, and saltpetre all showed large reductions. Turning now to the exports of chemicals, there is to be observed a gain of £361,084. in the values, being the difference between £2,458,265. in August last and £2,097,181. in the corresponding month of 1918. Bleaching powder has increased from £2,020. to £16,515., dyestuffs from £132,730. to £165,463., glycerine from £15,951. to £27,578., and manures from £165,903. to £470,597. Soda compounds show a slight decline from £377,039. to £332,068., but sulphuric acid has increased from £2,498. to £9,164.

It might be well to refer in this connection to the June statistics of Japanese trade, which show few signs of that capturing of markets of which we have heard so much of late. The only export in which there was a rise of any moment was raw silk. Imports continued to grow, the value of the manufactured goods being nearly twice as great as in June last year. In the first six months of the year an excess of imports of £22,000,000. took the place of an excess of £5,700,000. in the corresponding half-year of 1918.

CHLORIDE v. SULPHATE OF POTASH.

WHY CHLORIDE IS PREFERABLE.

(FROM A CORRESPONDENT.)

Sulphate of potash is sold in two qualities containing respectively 48.6% K_2O = 90.6% of sulphate, and 51.8% K_2O = 97.2% of sulphate, it is interesting to compare the following figures, which show the composition of these two salts and of chloride of potash containing 50% and 60% K_2O .

	Chloride of Potash.		Sulphate of Potash.	
	Containing 50% K_2O	60% K_2O	48.6% K_2O	51.8% K_2O
Chloride of Potash (KCl)	81.3	97.3	1.6	0.3
Sulphate of Potash (K_2SO_4)	—	—	90.6	97.2
Sulphate of Magnesium ($MgSO_4$)	0.3	0.2	2.7	0.7
Chloride of Magnesium ($MgCl_2$)	—	—	1.0	0.4
Chloride of Sodium ($NaCl$)	16.3	2.0	1.2	0.2
Sulphate of Calcium ($CaSO_4$)	—	—	0.4	0.3
Water (H_2O)	1.8	0.3	2.2	0.7
Non-soluble	0.3	0.2	0.3	0.2
	100.0	100.0	100.0	100.0

Chloride of potash thus contains a little more pure potash than sulphate, which has a certain advantage from the point of view of freight over long distances. Moreover, chloride of potash does not contain any salts of magnesium ($MgCl_2$ and $MgSO_4$), which easily absorb moisture, and have a bad effect on vegetation; it is also easier to transport, and has better keeping qualities.

The salt ($NaCl$) contained in chloride in a moderate proportion (2-16%) is likewise a great advantage for all soils yielding considerable quantities of potash in non-soluble combinations. Indeed, this salt is active enough to dissolve the potash contained in such soils and to enable the plants to assimilate it. This is a well-known fact, and has of late again been confirmed by Mr. D. K. Tressler (Bureau of Fisheries, United States Department of Commerce) in his essay published in *Soil Science* (VI., iii., 237-257, Baltimore, 1918). The introduction of chloride of sodium into the soil may, therefore, be considered an indirect kind of potash manuring. It may be added that sodium can to a certain extent replace potash in some plants, and that rather considerable quantities of sodium are indispensable for beet and sugar beet, for which reason these plants are sometimes manured with salt when this mineral has not already been applied together with the usual artificial manures. It is seen that chloride of potash contains only beneficial matter; the sulphate of calcium can even increase the solubility of potash in certain lands.

Sulphates of potash, apart from the disadvantages already stated, have the added great defect that, owing to disaggregation and the absorption of potash by the plants, they leave considerable quantities of sulphuric acid in the soil. This sulphuric acid may be very harmful, especially in soils that are poor in lime or badly aerated, and still more so on land suffering from both these defects. Chloride of potash is cheaper per unit than sulphate of potash, which is one more point in favour of the former.

As to the use of potash for the manuring of cotton plants, the potash syndicate itself states in a published pamphlet that the United States prefer natural salts for such manuring, which proves that neither chlorine nor sodium, both of which are found in natural salts, have a harmful effect on the cotton plants. Coffee trees, may without hesitation be manured with chloride of potash, which for this particular purpose is in every way equal to sulphate of potash.

For the manuring of tobacco and sugar cane, chloride of potash is only inferior to sulphate when it is applied very late—viz., shortly before planting. When chloride is applied a few months, or at the latest seven to eight weeks before planting time, it is in every way equal to sulphate. (All potash manures, sulphate included, should be applied before the sowings, so that the full benefit of the cultivation preceding the sowings may be secured, for the potash will then penetrate uniformly into the soil.) As to fruit trees, such as lemon, orange banana trees, etc., chloride of potash is fully equal to sulphate of potash if it is applied some time before the plants push through the soil in the spring.

A significant testimonial in favour of chloride has been given by the potash syndicate, which says in a pamphlet published last year: "The farmers abroad are restricted to the use of chloride of potash, which can be applied to most plants, and can be carried at low freights over long distances, on account of its high percentage (50-60% of pure potash.)"

THE BRITISH ASSOCIATION.

THE meetings of the various sections of the British Association, after being suspended since 1916, were resumed this year at Bournemouth, the meetings continuing from Tuesday, September 9, until Saturday, September 13. In past years the main Presidential address to the Association has been delivered before the business of the various sections began, but this year the Presidential address of Sir Charles Parsons, F.R.S., was delivered in the evening of September 9, whilst the sections began work in the morning.

CHEMICAL SECTION: PRESIDENTIAL ADDRESS.

In his Presidential address to Section B (Chemistry), Professor P. Phillips Bedson said:—

In again taking up the work of this Section, after an interval of three years, a discontinuity without parallel in the annals of the Association, it is natural that our thoughts should turn to the past, and in so doing we are reminded of the gaps in the ranks of those who were accustomed to contribute to the work of our Section. In 1916 we met under a shadow caused by the death of Sir W. Ramsay, whose genius has added in so many ways to our science. And to-day we have to record the loss of one who in his long life contributed in a variety of ways to the advancement of chemistry, and to whom we owe an addition to the number of elementary substances in the discovery of thallium, one of the early fruits of the use of the spectroscope. The chemistry of the rare earths has been especially illumined by the researches of Sir William Crookes. With physicists we would join in a tribute to the memory of Lord Rayleigh, amongst whose experimental researches is one of special interest to chemists—namely, the revelation of the existence of argon, of which discovery Sir J. J. Thomson has recently written that it was not made “by a happy accident, or by the application of new and more powerful methods than those at the disposal of his predecessors, but by that of the oldest of chemical methods—the use of the balance.”

In this connection it is but right that, despite the feelings engendered by the war, I should refer to the passing of two great chemists—Baeyer and Fischer. The former died some two years ago, and the latter within the past few months. Each of them has advanced by his experimental researches the progress of organic chemistry, and has brought illumination into many of the obscure departments of this branch of science. The field of investigation latterly cultivated by Fischer, has revived an interest in the “vital” side of organic chemistry as distinguished from the study of the chemistry of the carbon compounds. Moreover, there are many British chemists, amongst them some of the most distinguished, who, as students received guidance and inspiration from the teaching of Baeyer or of Fischer, and with them we gratefully acknowledge our indebtedness.

Jubilee of the Periodic Law.

Fifty years ago Mendeléeff communicated to the Russian Chemical Society a memoir which has exercised a profound influence on chemical philosophy, and continues to serve as a guide in the interpretation of research and speculations on the nature of the elements. Without entering on the somewhat vexed question as to whom should be assigned the credit of the discovery of the Periodic Law, I trust I shall not be considered unmindful of the claims of Newlands, by adopting the traditional history, and, as is usual, associate this discovery with the name of Mendeléeff, and consequently we may look on this year as the Jubilee of the Periodic Law. Although there is already abundant special literature dealing with this subject, and the periodic system has been assimilated into the teaching of the science and is dealt with in the text-books of chemistry, in some of which it forms the basis of the system employed in the exposition of the facts and theories of inorganic chemistry, still it appeared to me that I might utilise this as an opportunity of passing in brief review some of the features of the rise and development of the “Periodic Law.”

The memoir, made known to the non-Russian reader by the abstract in German, shows the principle of periodicity—viz., the recurrence of similar properties at regular intervals with increase in the magnitude of atomic weights, the possibility

of utilising the atomic weights as a basis of the classification of the elements, the necessity for the revision of the values thus assigned to the atomic weights of certain elements, and finally that the scheme demanded for its completeness the existence of many new elements.

The later writings of Mendeléeff contain the mode of tabulating the elements in the form usually adopted in chemical text-books, portraying the principle of periodicity and showing the grouping of the elements into natural families. But undoubtedly the clearest demonstration of the association between the atomic weights and the physical properties of the elements is that exhibited by the curve of atomic weights and atomic volumes, which is an outcome of the independent studies of these relationships by Lothar Meyer, and, as is well known, shows the members of the natural families of elements occupying corresponding positions on the curve. This curve, with its undulations, corresponding to the series of the elements, has contributed to impress on the mind of the student the relationship between the properties of the elements and their atomic weights, and may have exercised an influence in drawing attention to the relationships which the attempts of the earlier workers in this field were not successful in doing.

Mendeléeff's Table of the Elements was just beginning to figure in the teaching of chemistry in my undergraduate days, and, together with the speculations underlying it, aroused considerable interest and proved an incentive and inspiration for experimental inquiry. Foremost in this country amongst those who by their writings have contributed to spread a knowledge of Mendeléeff's speculations was my fellow-student, Carnelley. His experimental investigations added materially to our knowledge and definition of the physical properties of elements and compounds, which further emphasised the periodicity in the relation of the atomic weights to the properties of the elements, and have provided data from which curves, resembling in contour the atomic volume curve, have been set up.

A valuable guide in fixing the atomic weights of the elements has been the specific heat which, as the discovery of Dulong and Petit showed a hundred years ago, varies in the case of solid elementary bodies inversely with their atomic weights; or, as is more usually expressed, the solid elements have the same atomic heat. The investigation of the exceptions to this empirical rule brought out the fact that the specific heat is influenced by temperature, and the study of the influence of low temperatures led Sir James Dewar to the discovery that at about 50° Absolute the atomic heats of the elements are a periodic function of the atomic weights. Further, the graphic representation of this relation gives a curve very similar in its course to that of the atomic volume curve. So that the specific heat is another of the physical properties to fit into the periodic scheme.

The necessity for a revision of the atomic weights of certain elements, as pointed out by Mendeléeff, has induced several workers to direct their energies to the solution of the problems indicated, so that in our present-day tables many of the anomalies of position and sequence which existed in the earlier schemes have disappeared. Tellurium has still resisted all attempts to bring it into order, with an atomic weight less than that of iodine, which its association with sulphur and selenium demands. The interesting attempts to decompose tellurium have so far remained unfruitful.

But undoubtedly the most fascinating feature of the periodic system in that “it allows the discovery of many new elements to be foreseen.” This and the manner in which Mendeléeff, in full conviction of the truth of the “Periodic Law,” boldly assigned properties to those elements required to fill the blank spaces in the table of the elements, and the verification within twenty years in three instances of these prophetic specifications have contributed to the recognition and firm establishment of the “Periodic Law” as an article of belief in chemical philosophy, and to make it the main-spring and inspiration of the greater part of modern inorganic research.

Discovery of Argon.

The discovery of argon, the announcement of which formed a notable feature in the proceedings of the Association at the Oxford meeting in 1894, and the recognition in it of an element with an atomic weight of 40, raised doubts in the minds of some as to the validity of the scheme of the elements

based upon the Periodic Law. It was indeed a time of testing the faith. The suggestion that argon would prove to be a modified form of nitrogen was brushed aside by the incontrovertible establishment of it as an element, endowed only with specific physical properties and distinguished from all known elements. But argon was not destined to enjoy a splendid isolation for long. The researches of Sir W. Ramsay soon brought helium to earth, and he and his colleagues provided a number of companions for argon. So, in a very short period, was recognised the existence of a group of gaseous elements forming a natural family, whose molecules are monatomic, the members of which are distinguishable by their spectra and atomic weights, but are all in agreement in their unreadiness to take part in any chemical change. This inertness or nonvalence provided a simple means of reconciliation with the periodic scheme of the elements, as all that was required was simply to add to the eight groups of the table of elements a zero group containing helium, neon, argon, krypton, and xenon, and with niton, the emanation from radium, as a recent addition. If we are to accept Mendeléeff's suggestion, the zero group should contain a member lighter than hydrogen, in Series I., and in a zero series a still lighter representative of the elements of the zero group, which he has postulated as the 'ether' of the physicist.

Thus the discovery of argon has formed a starting point in the development and a justification of the natural system of the elements, but it still remains, to make the tabulation complete, that provision should be made for the accommodation of the rare earths. The paper published by Werner in 1905, under the title "A Contribution to the Development of the Periodic System," shows how this can be satisfactorily accomplished.

The elements of the argon group form a valuable extension to the periodic system, and the knowledge acquired in the investigation of these substances has proved serviceable in the solution of problems in the realms of science and of industry. The knowledge of the properties and behaviour of helium was destined soon to play a part in the solution of the riddle of the radio-active elements, whilst it is specially noteworthy that argon, the "idle one," should have been pressed into industrial service.

This fact suggests the thought that idleness has its uses, and at the present time how satisfactory would it be were we able to find useful application for a quality which appears to be plentifully and widely distributed in this country.

The history of helium is still more astonishing, for not until thirty years after its existence had been surmised from spectroscopic observations of the sun was this element found to have a terrestrial existence, and now, as one of the achievements of science during the war, we may look on its production in bulk as a commercial proposition. Moreover, we are told "that the advances made in the production of helium warrant the opinion that had the war continued after November 11, 1918, supplies of helium at the rate of 2,000,000 cubic feet per month would have been produced within the Empire and the United States, and helium-filled aircraft would have been in service."

Some of the speculations that the periodic system of the elements has given rise to have been the subjects of communications to this Section.

At the Aberdeen meeting Carnelley, whom I have already mentioned as an ardent worker in this field, gave an account of a scheme based on the conception that the elements are composite, having relations similar to those exhibited by the paraffin hydrocarbons and the isologous series of radicals derived from them. He regarded the elements, other than hydrogen, as made up of two simple elements, A and B. A he identified with carbon, with the atomic weight of 12, and B was assumed to have a negative atomic weight of 2.

In the following year, at Birmingham, Sir W. Crookes devoted his address to this Section to an exposition of his ideas of the 'Genesis of the Elements,' a subject to which he on many subsequent occasions returned, and amplified in the light of recent discovery. The process of evolution of the elements from a primal "protyle" is depicted as taking place in cycle after cycle, in each cycle the 'unknown formative causes' scattering along its journey clusters of particles corresponding to the atoms of the 'elements,' forming in this way a series such as that beginning with hydrogen and ending with chlorine; a repetition of the movement under somewhat altered conditions giving rise to a series of similarly related elements, and thus homology, which is shown by the members of the natural families, is provided for.

The investigations of Sir J. J. Thomson on the discharge of electricity through gases have established the divisibility of the atoms, and in his "Corpuscular Theory of Matter," he has given us conceptions of how atoms may be constituted to provide a series so related that they reflect, it not reproduce, many of the chemical characters of the elements and their periodic relation to atomic weights.

With the discovery of radium and its remarkable properties we have been brought in contact with an element undreamt of in our philosophy. The interpretation of the results of the investigation of this element has called for drastic changes in our conception of an element. The pursuit of the researches of the radio-active elements, guided by the theory of the spontaneously disintegrating atom propounded by Rutherford and Soddy, has served to reveal facts which lend a special emphasis to many passages in the address of Sir W. Crookes to which I have already referred.

For instance, the passage in which he said: "Should it not sometimes strike us, chemists of the present day, that after all we are in a position unpleasantly akin to that of our fore-runners, the alchemists of the Middle Ages? The necromancers of a time long past did not, indeed, draw so sharp a line as do we between bodies simple and compound; yet their life-task was devoted to the formation of new combinations, and to the attempt to transmute bodies which we commonly consider as simple and ultimate—that is, the metals. In the department of synthesis they achieved very considerable successes; in the transmutation of metals their failure as a matter of history."

Or again, when he propounded the question, "Is there, then, in the first place, any direct evidence of the transmutation of any supposed 'element' of our existing list into another, or of its resolution into anything simpler?"—a question to which he, Sir William Crookes, was at that time forced to reply in the negative, whereas to-day many instances might be cited in support of an affirmative answer to this question. Radio-activity has supplied a method of analysis—radio-active analysis—surpassing in delicacy any of the previously known methods for the examination of material substance; the application of these methods has not only added to the list of elements, but also new classes of elements. First, elements indistinguishable and inseparable by chemical means, yet differing slightly, but definitely in their atomic weights. The existence of these "isotopes," as Soddy styles them (a name giving prominence to the fact that such elements occupy the same place in the table of the elements), demonstrates that absolute uniformity in the mass of every ultimate atom of the same chemical element is not an essential, but that "our atomic weights merely represent a mean value around which the actual atomic weights of the atoms vary within certain narrow limits."

Whether the possibility of separating isotopes, recently suggested by Dr. Lindemann and Dr. Chapman, will be found capable of experimental realisation, must be left to the future to decide; in fact, in this matter we must adopt the attitude, prevalent in other than scientific circles, of "wait and see."

The investigations in the field of radio-activity have further brought to light that identity in atomic weight may be associated with difference in chemical properties, revealing the existence of a further class of elements for which Dr. Stewart suggests the name "isobares." Further, Dr. Stewart considers that isobaric elements are to be found not alone amongst the radio-active, but some of the normal elements exhibit properties which may be explained on the assumption that they are isobarics. Thus the compounds formed from iron are regarded as indicating the existence of three irons, all having the same atomic weight. One of these, termed ferrium, is trivalent; one, ferrosium, is divalent; whilst the third, feron, is inert and takes no part in chemical changes. The three are under certain conditions mutually interconvertible. This last condition does not apply in the case of the radio-active isobares.

The elements are to be regarded as divisible into three classes: (1) Isotopic elements, each set of which have different atomic weights but identical chemical properties; (2) isobaric elements which have identical atomic weights but different chemical properties; (3) normal elements which differ from each other both in atomic weights and chemical properties.

The discovery of X-rays may be acclaimed as having added a new sense to aid us in our investigation of material objects, and to their innumerable services may be reckoned the results which have followed from the investigations of the X-ray spectra of the elements by the late Lieut. Moseley, whose

death in Gallipoli in 1915 is one of the many tragedies of the war specially deplored in the scientific world. From the analysis of the X-ray spectra, Moseley has shown that for each element a value can be deduced, which is styled the atomic number and which represents the space in the atomic table the element should occupy. The researches of Rutherford and Andrade on Lead and Radium B have proved that "isotopes" have the same atomic number. Whatever may be the ultimate explanation of the meaning of the atomic numbers, their experimental determination has already proved valuable in the solution of some of the anomalies of the Periodic Table. In addition to the case of isotopes, just referred to, the number of elements between hydrogen and uranium is fixed by finding 92 as the atomic number for uranium, and further, Moseley's work has revealed that the atomic numbers are in agreement with the order of the chemical sequence, rather than the order of the atomic weights, which is of special interest and value in the cases of tellurium and iodine, and of potassium and argon, the decision in each case proving a welcome support to the position in the table assigned to these elements on chemical considerations.

Again, Moseley's atomic numbers remind us of the arrangement of the elements adopted by Newlands in his communication to the Chemical Society of 1866, in which he set forth the "Law of Octaves," the precursor of the Periodic Law.

In concluding this brief sketch, cognisance should be taken of the speculations of physicists as to the structure of the atom. Already several models of the atom are in the field which leave the uncuttable Daltonian atom far out of view; still in a measure they help to an understanding of some of those regularities exhibited by the elements, and set forth in the natural system. Valency and its vagaries, which we are accustomed to describe by phrases such as "variable valency," "selective valency," and the like, still call for a full explanation.

Relation of Chemical Industries to the State.

I purpose now to direct attention to matters of another nature, which appear to me of interest to chemists, and to that extent have a bearing on the welfare of chemistry in this country.

Among the numerous revelations and surprises of the past five years has been the realisation on the part of the public and the Government of the importance of the chemical industries to the national well-being. The apathy and indifference of pre-war times were replaced by an apparently lively interest in things chemical, and there was what in the religious world would be styled a revival.

Politicians, and Press in all its varied forms, daily, weekly, monthly, and quarterly, took up the subject of our industrial insufficiencies and emphasised in various ways the importance of research in connection with our industries. Again, the coal-tar colour industry furnished, as it had done again and again, some thirty to forty years ago, the text from which research and its importance was preached. This time the reiteration had the effect that the "aniline phantasm, as I have seen it described, was recognised as a 'key industry,' important to the vitality of the manufacture of textiles; with the result that the Government, discarding its fiscal policy, was induced to subsidise the enterprise for the manufacture of dyes and other coal-tar products. The negotiations preceding the formation of the "British Dyes Co., Ltd.," have been remarkable as revealing that in the eyes of some, at any rate, special knowledge is a "dangerous thing," and, in fact, was deemed sufficient to exclude its possessors from a seat on the directorate. This is all the more remarkable as the history of similar enterprises in Germany shows the personnel of the directorates to be made up of university-trained men, in not a few instances of professors. So that in Germany academic distinction and theoretic learning are not considered as excluding the possession of commercial acumen and those other qualities needed in a successful man of business.

In the early stages of the war the demand for explosives was met by the expansion of already existing factories, the increase in staff of which called for many additional men with chemical training, a call which became unprecedented and insistent when the national factories were founded, so that men and women with a chemical training found an opportunity of putting the knowledge at the service of their country. And in not a few instances those who, for financial reasons, had at the close of their college career taken up a less congenial employment were able to return to the practice

of chemistry, for which in their student days they had specially fitted themselves.

In the foreword of the publication "Reports on Costs and Efficiencies for H.M. Factories," issued by the Ministry of Munitions, we are told "when it was decided to commence the erection of new and national factories, and an attempt was made to collect from existing factories the necessary technical data and assistance, did it become evident that, due to the extraordinary demands of the war, there was—practically throughout the entire country—a regrettable lack of available accurate technical data, and an even greater lack of trained technical men—more particularly chemical engineers."

To anyone acquainted with the conditions existing in this country in pre-war days, the lack of "trained technical men" is no matter of surprise. In fact, one cannot fail to be astonished at the phenomenal development of chemical manufacture which has taken place under the directing influence of Lord Moulton, in response to the call from Army and Navy. That men were found capable of taking a part in these varied undertakings, cannot, at any rate, be credited to the encouragement which the teaching of chemistry or the students of the science had received from those directing industries, which employ or should employ the services of chemists. It is no uncommon experience to find the chemist employed simply in the analytical testing of raw materials and manufactured products, and even in the working of processes under their control the potentiality of the chemist is not utilised to the full, as is evident from the following, which is a quotation from the Preface to the brochure, issued by the Ministry of Munitions, to which I have already referred: "Since the beginning the policy of the Department with regard to our national factories has been to aim at maximum efficiency in respect of cost and usage of materials."

"For this purpose the greatest efforts have been made to place before all those who are in any way responsible for control, full details concerning the working and costs of the factories. This was rather an innovation in the field of chemical manufacture, as until comparatively recently, either intentionally or through negligence, it was customary at many chemical plants to keep the chemists in complete ignorance not only of the cost at their plants but also even of the efficiencies."

"It is amazing that manufacturers can expect improvements in chemical processes when their chemists are kept in ignorance of such vital facts."

"It has happened very often that as soon as detailed figures were seen by chemists at a plant, important alterations and improvements have at once been suggested, the need for which would otherwise never have been noticed."

The condition of service indicated in the passage quoted, together with the low scale of remuneration which obtained hitherto in chemical industries, help to explain the scarcity of the kind of scientific labour referred to in the quotation I have made from the "Foreword."

But are we not told and invited to believe that all this is changed, that the records of the magnificent achievements of British chemists in the war have so educated the people and, may we say, the Government also, that the practitioners in chemistry will no longer find it essential that in describing their vocation they should be required to add, unless for special reasons, such prefixes as "analytical," "research," "scientific," or "engineering" to the word chemist, secure in the feeling that by describing themselves as "chemists" their standing, training, and profession will be correctly understood.

Still a feeling akin to despondency, if nothing worse, is pardonable, when realising the fundamental importance of chemistry to our industries, and the thousand and one ways chemical research has ministered to the amenities of our every-day life, there should exist not alone in the mind of the general public, but of the educated also, such a lack of information as has been revealed during the past few years. To wit, the myth woven into the history of the production of glycerine, the confusion in the minds of legislators between phosphates and phosgene. More serious, however, is the fact that the method of investigation employed by the chemist is so little appreciated or understood as to lead one to imagine that the discoveries and achievements are the results of a species of legerdemain. The production of new colours, a succession of happy thoughts, and that "by an accident the secret of synthetic indigo was unlocked." This last is a quotation from a review entitled, "The Value of Scientific Research," published some three years ago, and is typical of

much that passes muster in appraising the value of chemical research. That the unravelling of the constitution of indigo which occupied Baeyer and his pupils some thirteen years, the account of these investigations covers some 180 pages of Baeyer's collected works, should be summarised in this way appeared to me to call for a protest. My protest was made and I attempted to put the matter in the correct light, showing the synthesis of indigo to be, indeed, a brilliant example of the value of theory and of a practical illustration of the importance of the chemist's conception of the Architecture of Molecules, as exemplified by Kekulé's theory of the constitution of benzene. The protestation evoked a reply from a correspondent, signing himself D.Sc., Ph.D., who sought to justify the description of the revelation of the secret of synthetic indigo by reference to an accident which occurred in the investigation of the processes for the manufacture of phthalic acid and which certainly greatly facilitated the production of this substance, an intermediate in the manufacture of artificial indigo. So, if the initiated emphasise the unessential, why should we blame the layman and be surprised that well-ordered and planned design should appear to be but the workings of chance, for every such achievement is a witness to the conquest of well-founded theoretical speculation.

But I do not wish to conclude on a despondent note, nor is it right that I should do so, in view of the many activities operating for the promotion of scientific research, and of such evidence as that supplied by the magnificent endowment of the Chemical Department of the University of Cambridge, all of which are evidences of what we may reasonably hope to be a happy augury for the future of chemistry and chemists in this country.

CHEMISTRY AND THE WAR.

Sir William Pope, in an address on this subject, said that the sudden establishment of a state of war between two or more modern nations involves certain preliminaries. We might assume that the most peaceful of the Great Powers were in possession of carefully worked out and detailed plans for necessary action in the event of attack by other similar Powers; foremost in the elaboration of such plans was necessarily the data available as to the possibilities of success in any threatened war. We could not imagine the gauntlet thrown down between several world-Powers until the aggressor had made certain, so far as certainty was humanly possible, of ultimate victory. The equilibrium existing between all the relations—commercial, technical, and scientific—of modern life as between different nations was so complex and so delicate that its derangement by a condition of war must lead to results which could not be foreseen; the dangers of the unforeseen might be minimised by certainty of success. Confidence in success could only be attained after years of consultation with the whole of the instructed talent of an Empire had indicated precisely the most favourable moment for aggressive action. War was too serious an enterprise to be embarked upon merely because it might seem desirable from some internal or external political motive; it could only be undertaken when its successful conclusion seemed assured. In these circumstances we could not doubt that one of the most important contributories to the recent war was the striking contrast between the material resources of Germany and of the rest of Europe. In no domain was this contrast more evident than in that of the chemical industries; no branch of scientific technology was more immediately concerned with the arts of war than that which included all the great industries in which chemistry takes a leading part. What was the position of our chemical industries in 1914? Germany was at this time in possession of well-established organisations for the manufacture of coal-tar colours; she provided the great bulk of the artificial dyestuffs consumed throughout the world. Small installations existed in this country, France, and America, but the scale upon which operations were conducted outside Central Europe was insignificant. The outbreak of war was the signal for the conversion of all these great colour-making factories into manufacturing of high explosive. The British demand for high explosive rose to about 1,000 tons each of T.N.T. and picric acid and about 3,000 tons of ammonium nitrate per week. The complex facilities for the manufacture of these enormous quantities of material were practically non-existent at the beginning of the war in this country, but Germany was in a position to meet all her military demands by a mere rearrangement of her coal-tar colour works. So lacking were our means for utilising the great source of wealth represented by coal-tar

that during the first year of war 80 per cent. of our output of T.N.T. was derived from toluene contained in Borneo petroleum. The British demand for cordite, which had for long constituted the standard propellant for both large and small projectiles, rose to about 2,000 tons per week; the commencement of the war found us with neither works nor chemists for the manufacture of these quantities. A number of important points arose which must have engaged the attention of the German authorities. One of the chief essentials to a modern army or navy was quinine; 97 per cent. of the world's quinine production came from the Dutch colony of Java, and its import into Europe was practically under German control. A large number of other essential pharmaceutical products—such as salicylic acid, salvarsan, and local anaesthetics such as eucaine and novocaine—were made almost entirely in Germany. The war with Germany stopped our provision of all these essentials. Most of the fine photographic chemicals used in development and in the preparation of panchromatic plates were made almost exclusively in Germany; the initial lack of these constituted a heavy handicap to our air photographic service. Many of the essentials to the manufacture of special steels necessary to modern warfare—such as tungsten and the like—came to us from Germany. The control which Germany had secured over the manufacture of such products as coal-tar colours, pharmaceutical chemicals, and the like, enabled her to throw her enemies into confusion by a purely economic method at the outbreak of war; this initial advantage was gained, whilst entirely satisfactory arrangements were provided, by the stoppage of exports, for the manufacture of the necessary quantities of explosives, etc., at home. Another advantage was, however, derived from the advanced development of the German chemical industries.

The fundamental essential in the manufacture of explosives was nitric acid or its salts; the rifle and the large gun would become useless if we were no longer able to obtain these substances. The world's supply of nitric-acid salts had been hitherto obtained from the Chili saltpetre of South America; it is obvious that Germany could not go to war whilst dependent upon an overseas supply of this absolute necessity. It was known that previous to the war Germany was busily engaged upon the perfection of methods for manufacturing nitric acid and its salts from atmospheric nitrogen; this work came to a successful head in Germany not long before the outbreak of war, and she then became independent of overseas supplies of nitric acid. Was it to be doubted that this development of chemical industrial effort was not a factor in the declaration of war?

Whilst during five years of war this country succeeded in expanding its previously small installations for fine-chemical manufacture to such an extent that they became of sufficient magnitude to meet the immense demands for military explosives, one essential difference was observable between the German practice and that initiated to fulfil the corresponding war needs in this country. The German establishments were developed on a peace footing, and produced materials consumed by the whole world; they paid heavy dividends, and were a source of great national wealth in time of peace. At the same time, they were available for mobilisation for war production of explosives at short notice. The whole world, in fact, paid for the erection and extension of the vast explosives factories which made Germany so formidable in 1914; the British Empire paid for the German munition factories just as it paid for Gretna. Now that war was over, the German factories remained intact, and could revert immediately to their former task of providing our Empire with dyes, pharmaceutical and photographic chemicals, etc., as a dividend-paying proposition. The great German synthetic nitrogen products works, developed so as to render Germany independent of sea-borne nitrates for explosives manufacture, could now produce a considerable proportion of the nitrates and ammonium salts needed by Europe as agricultural manure. During the war the German synthetic nitrogen products factories had been greatly extended; these extensions constituted a valuable asset to the German commerce of the near future.

In this country it had not been possible to build up a chemical manufacture for war purposes which could be at once diverted to production for peace requirements. Explosives factories had had to be put up hurriedly for war production alone; the organisation could not be developed at short notice in such a way that the factories acquired any considerable after-war value. Thus the vast installation at Gretna was now practically on the scrap-heap. Whilst the German chemical industries emerged from the war in a stronger position than they held before, our own remain

much where they were. The causes which had placed the German chemical industry in the commanding position which it had so long occupied had been repeatedly discussed, and need not be considered on the present occasion; one point, however, might be insisted upon—Germany had never commanded any monopoly of scientific talent which had enabled her to secure supremacy in fine-chemical manufacture; in fact, a disproportionately large number of German technical products were discovered by scientific workers in Great Britain. A remarkable illustration of this fact occurred in connection with the materials which had been used in chemical warfare. Thus phosgene was discovered by John Davy in 1812, but only insignificant quantities had been made in this country; it was manufactured in considerable quantities in Germany for use in coal-tar colour preparation. The best and most economical methods of manufacture had been worked out on a peace basis in Germany; phosgene was an extremely poisonous substance, and was early used by the Germans in gas warfare. Large quantities of phosgene were used by us for the same purpose, but only after the delay caused by the necessity of time for working out the most convenient methods of manufacture and the construction of plant. Again, chloropicrin was discovered by James Stenhouse in 1848, and was highly poisonous; the Germans used it as a toxic material in gas warfare, being able to prepare it in quantity in the dye factories; and we, after the necessary delay for working out methods and installing plant, also used it in large quantities. The most powerful agent of all used in gas warfare, mustard gas, was discovered by Frederick Guthrie in 1860; the Germans were able to make it in their colour factories by an extremely complicated method, and used it against us in June, 1917. It took us about a year to work out and install a method of manufacture—much superior, it is true, to the German procedure—with which to arm the necessary retaliatory measures. All the above substances were British discoveries, but at the outbreak of war we had no facilities for their large-scale manufacture, whilst the flourishing coal-tar colour industry of Germany was able to provide them in quantity. Now that serious endeavours were being made to place fine-chemical manufacture on a proper basis in Great Britain it should be the duty of all interested to insist that the great schools of experimental science in the country should be financed on such a scale as to enable them to train efficiently the vast amount of young inventive talent which the war has shown to exist among us; only by so doing would it be possible to secure the large numbers of highly trained young scientific men who would be needed not merely for the purpose of gaining the knowledge required for the manufacture of articles of commerce already supplied by Germany, but for producing new inventions which would carry us in front of German effort. The record of Great Britain in chemical discovery was one of which she may well be proud, and many chemical industries now well established in Germany might be justly claimed as based entirely upon British discoveries. The coal-tar colour industry was initiated by the discoveries of Perkin, and was, indeed, established by him in this country before it was ultimately transferred almost wholly to Central Europe. Again, about a century and a half ago Henry Cavendish discovered that atmospheric nitrogen and oxygen could be caused to combine at the high temperature of the electric spark; this process, carried out on a minute scale in the laboratory by Cavendish, had been put into large-scale operation in Central Europe, and was used for the manufacture of huge quantities of nitric acid in Germany. Here, again, the development of a great scientific discovery made in this country had been left to Germany, and none of the practical fruits of the discovery have been gathered in Great Britain.

The whole history of the war consisted of a series of sequences in which some sudden military emergency had been met by rapid British scientific invention put into rapid practice by British technical effort. It can never be said, again, that this country is deficient in scientific skill or in technical ability.

It was, of course, obvious that the lessons which have been so forcibly brought home to us during the war must be applied by us in peace if the history of the past five years was not to be repeated. We needed the building up of all branches of chemical industry, and, to the promotion of that end, a great extension of the facilities for scientific education available in this country. In one respect at least the British Empire was in a highly favoured position; in one part or other it produced every raw material needed in its manufacture, although it had in the past left these sources of supply to be exploited by the foreigner.

In the near future one great danger threatened us. The large German colour works are again resuming their pacific manufacture of dyes and pharmaceutical products, and one of the foremost German dye manufacturers, Professor Carl Disberg, of Leverkusen, who helped his country valiantly in providing the materials for gas warfare, has just expressed the hope that he will be over in America again "very soon to see his old-time friends (*Journ. Indus. Engin. Chem.*, 1919, II., 509)."

We were on the eve of a great German propaganda movement for the purpose of rehabilitating the German chemist in the eyes of the world.

Discussion.

The PRESIDENT said that the science of chemistry has suffered more materially in the past than any other, by reason of lack of public and official recognition, but possibly after what had happened during the war, things would improve in the future. At times he thought they would, but at others he thought they would not. During the war it was impossible to fill the positions for which chemists were required, but now there were chemists wanting positions.

Professor H. E. Armstrong said he thought the paper ought really to have been read before the Economic Section. At times we were too prone to exaggerate the importance of chemistry in this connection relatively. Take the case of synthetic indigo. To him the marvel was, not that the Germans were successful as chemists in doing what they did, but that they were successful in exercising forethought 30 years in advance, and in seeing that there was a problem worth dealing with and spending any amount of money on from the chemical side. What we should ask ourselves was, why were the Germans such a long-headed nation, and we such a short-headed one?

At any time during the past 30 years we might have done what we had done during the war if there had been a sale for the products of the universities in the shape of chemists. Instead of that, too many students went to the bar simply because there was not a proper encouragement of them. He did not know whether there had been any advance in the attitude of manufacturers as a result of the war. He was inclined to think there had not been. The engineer and the chemist were not working harmoniously here, even now. They were in Germany. The engineer still thought too little of the chemist; he thought that he was the real man, and never gave the chemist a real chance. That state of affairs must be altered, and more particularly was it necessary to alter the outlook of the commercial man, or at least the education of the classes who were to be manufacturers and men of commerce. The question was whether they were likely to do that. There was some peculiar quality in the German which made him more receptive than ourselves. He had never been in the house of an English manufacturer, and met with the same culture that he had met with from similar men in Germany. People in this country would not take risks and look ahead, and be prepared not to have big returns at once. The Germans had worked out everything during the war, so that it would be of benefit to their manufacturers after the war, whereas we in this country were really worse off now than we were before the war.

SIR ROBERT ROBERTSON said that besides the training of chemists academically, there was an urgent need of technical training, and it was to be hoped that facilities would be given for that training. In his opinion, the training for an industrial chemist should be non-specialisation in the first instance, and a thorough grounding on the academic side, followed by a period in a factory, and then a return to some institution where he would receive guidance in technical training. In that institution he would be best left alone with simple appliances, and given the solution of a definite problem. In that way he would work out his own salvation, and if there was anything in him he would become a chemical technologist. That there would be a demand for this type of man in the future was undoubted, but at present, the outlook in regard to remuneration was deplorable.

SIR WILLIAM POPE in a brief reply, said he ought to mention that Sir Robert Robertson was previously responsible for working out the large scale manufacture of T.N.T., and that was a thing which every member of the nation could not be too grateful for.

CHEMICAL WARFARE.

In a paper before Section B (Chemistry), on Tuesday, September 9, Brigadier-General H. Hartley gave an exhaustive and interesting account of gas warfare and described the work of British chemists in this connection. Having explained that gas attacks were made in two ways, (a) in clouds, and (b) by projectiles, he mentioned that the first German gas attacks were made in 1915, when our troops were wholly or partially unprotected. In the first attack a great opportunity was missed by the Germans owing to the use of gas in low concentration and too small quantities, and even then the Germans failed to exploit the partial success gained in these attacks. We then formed a special brigade consisting of specially enlisted chemists, and from the formation of that brigade we liberated in France about 5,700 tons of gas, 25 per cent. being in the form of cylinder or cloud attacks, and the remainder in the form of projectiles. Development both on the part of the Allies and the Germans was then rapid. The German effort was directed to using little known organic compounds, hundreds of tons of complex organic derivatives, previously only prepared once or twice in a laboratory, being utilised. In 1916 chlormethylchloroformate (B.P. 105° C), with tonic properties similar to phosgene, was introduced and used against us. Later this was replaced by the trichloro compound (B.P. 128° C), which was used until the end of the war. As the well-known green cross shell filling, phosgene, was also introduced in trench mortar bombs. During the Arras battle of 1917, a variant appeared with asphyxiant properties, whilst in July, 1917, mustard gas made its appearance. Other varieties were introduced at various times. In the preparations for his attack in March, 1918, 90 per cent. of the enemy ammunition contained gas; it was never before used on such a scale, and from then until the end of the war both defensive and offensive operations were carried on by the aid of gas shells to a very considerable extent. A large number of extracts from a confidential report of General von Bulow, commanding the 1st German Army during the battle of Arras, dated 11-4-17, were read by Brigadier-General Hartley, which showed conclusively that our retaliatory measures in the use of gas had successful results. Other extracts from further German documents, were also read to the same effect. Then followed a discussion of the value of gas as a weapon in warfare, and a comparison of it with other weapons.

Coming to the work of British chemists, Brigadier-General Hartley said that researches were carried out in many laboratories, and a debt of gratitude was owing to professors and their assistants for the manner in which they worked on substances that were never pleasant, and often involved considerable risks. In April, 1915, we had only one plant producing liquid chlorine, with an output of 7 tons per week, but the energy of manufacturers enabled the first gas attacks to be made in September, 1915, and by December 31, 800 tons of gas had gone to France. Production increased steadily from that date, the output being: 1915—860 tons; 1916—5,150 tons; 1917—18,500 tons; 1918 (ten months) 15,500 tons. This, considering our unpreparedness, was a very satisfactory result. But comparison with the German output, thanks to their great resources, showed the importance of developing our organic chemical industry, otherwise we might find ourselves at the mercy of any power which had developed its resources in this respect and was prepared to take full advantage of them on the outbreak of a war. If any country dominated this industry as Germany did before the war, it was liable to become a standing menace to the peace of the world. More important even than offence was the means of defence against gas attacks, and it was difficult to over-estimate the value of the work of the anti-gas department under the leadership first of Sir William Horrocks, and later of Lieut.-Colonel Harrison. The latter gathered under him an enthusiastic group of young chemists and physicists, and the box respirator represented the joint results of their researches carried out under his inspiration, and controlled by his admirable practical judgement. He organised its manufacture on a huge scale, and it was a great testimony to his foresight and ability that, in spite of difficulties of production, supplies promised to France never failed. Altogether 55,000,000 respirators were produced by the Department, and of these, 19,000,000 were box respirators. Examples of the various types of gas mask, showing the stages in development, were exhibited.

Continuing, the author said that many chemists were employed in England and the theatres of war in advising on

technical matters connected with gas warfare, in organising gas defence, and in training and instructing the troops. That work had not been generally known or properly appreciated. The training of the men in the use of the respirators was as important as the design of it, because it gave them confidence in its use. The gas officer or chemical adviser in France had a very responsible post. In addition to his instructional and advisory duties he acted as intelligence officer so far as gas was concerned, investigating every attack to discover means of improving our defence, and collecting evidence of the result of our own gas operations. All new appliances were sent to him for a service test and criticism. Their work was of great value, as, being in constant touch with first-line conditions, they were in a position to criticise new appliances and to foresee future needs. Without their criticism and advice, progress would have been far slower and less certain. A field laboratory was formed in April, 1915, for investigating enemy material and solving urgent problems. The success of the laboratory owed much to the mechanical ingenuity and critical ability of Lieut.-Colonel W. Watson, the first director of the laboratory, and to the resourcefulness of his successor, Lieut.-Colonel B. Mount-Jones, who was mainly responsible for the chemical work from its formation. The instruction given at the gas schools was able to counteract to a great extent the disadvantage under which we suffered, owing to the general lack of scientific training among all ranks.

In conclusion, the author said that had the enemy foreseen the results of his treachery in introducing this new weapon in April, 1915, it would never have been employed. As it was, it provided another example of the German lack of foresight and their underestimation of their opponents, which might have delayed a decision, but only to make it the more complete and crushing in the end.

PRESIDENTIAL ADDRESS TO SECTION A
(Mathematical and Physical Science).

PROFESSOR A. GRAY in his address to this Section, dealt with some of the lessons which war has or ought to have taught our country and those who direct its policy. To a larger extent, of course, it was general in character and related mainly to engineering matters, but some of his points have an indirect bearing on the chemical and allied industries. In the first place he contended that had there been any truly scientific element in the personnel of the Government, attention would have been directed at a much earlier period to our hopeless state of unpreparedness for the storm which was gradually gathering up against us on the other side of the North Sea. This lack of scientific knowledge at the beginning of the war was responsible for a loss of life and treasure from which it will take us long years to recover, and which he could wish, seemed to weigh more heavily on the minds and consciences of politicians. The one single idea of our mobilisers was to send men to the trenches to kill Germans. The cause of the prevailing neglect of science, with all its pernicious results, was that almost all our political leaders had received the most favoured and fashionable form of public school education, and were without any scientific education. As things were at present, eminence in science was no qualification, it would even seem to be a positive disqualification, for any share in the conduct of the affairs of this great industrial country. Take the case of the dyes industries: the publicists and the good business men—the supermen of the present age—who wished to control and foster an industry which owed its very existence to an English chemist, refused to have on the committee which was to manage this important affair any man of scientific eminence, and no remonstrance had any effect. These great business men were, as a rule, not scientific at all. They were all very well for finance; in other respects their businesses were run by their works managers, and in general they were not remarkable for paying handsomely their scientific assistants.

While scientifically educated men, whether doing special work or acting as officers, had been held of far slighter account in the services than they ought to have been, for physicists as such there had been little or no recognition, except when they happened to be ranked as research chemists. These latter received their recognition in consequence of the existence of the Institute of Chemistry, and he was extremely glad that something was being done to found an Institute of Physicists. He was glad that something was being done at last for the organisation of scientific research. The movement had started well in several, if not all, respects, but there were one or two dangers to be avoided. There was, for instance, too

much centralisation aimed at. Everything was to be done from London; a body sitting there was to decide the subjects of research and to allocate the grants. There might be a good deal to be said for that in the case of funds obtained in London, but apparently already existing local incentives to research were to be transferred to London. The Carnegie Trust for the Universities of Scotland inaugurated a scheme of research work in connection with those Universities. The beneficiaries of the Trust, it was well known, must be students of Scottish nationality, but now, so far as chemistry and physics were concerned, it had been proposed, if not decided, to hand over to the organisation in London the making of awards, a process of centralisation which would probably not end with these subjects. He ventured to protest against that proceeding because the more incentives and endowments of research that existed, and were administered in the provinces, the better.

AUTOCLAVE FAILURES.

THE fiftieth annual report for 1918, issued by the Swiss Society of Steam Boiler Owners, Zurich, gives particulars of the failure in service of two autoclaves, or digesters. In one instance, a digester of semi-steel (*fonte d'acier*—steel casting?), which had been in service in a chemical works, was distorted, due to being overheated; as will be seen by Fig. 1, the spherical end dropped about the centre line and cracked, and the liquid content escaped into the fire-box. The digester was of Swiss manufacture; it was directly heated at a distance from the grate of 0.52m. (20 $\frac{1}{2}$ in.). The lower part internally had a thick deposit, due to the service required of the apparatus. The heavy deformation, 116mm. (over 4 $\frac{1}{2}$ in.) for a wall thickness of 90mm. (3 $\frac{1}{2}$ in.), must evidently have been the result of submitting the apparatus to a very high temperature. The apparatus was manufactured in 1915; the maximum registered pressure was 60 atmospheres; the explosion occurred at a pressure of 48 atmospheres and at a temperature of 265° C. The society condemned the digester, and had it replaced. In the case of the new one, they recommended placing the mixing device close to the bottom and increasing the distance between the grate and the digester.

In another chemical works, the bottom of a grey cast-iron digester, directly heated, also gave way (see Figs. 2 and 3). The crack produced by the explosion had, in the cold state, an opening of from 5mm. to 10mm. ($\frac{1}{8}$ in. to $\frac{3}{8}$ in.) in its central portion and a length of 0.5m. (19 $\frac{1}{2}$ in.). The liquid in the apparatus ran out in the fire-box. The digester was at a distance of 0.55m. (21 $\frac{1}{2}$ in.) from the grate. The apparatus, of foreign manufacture, was first used in the making of explosives, but this had been changed a few days before the accident, and fortunately so, for otherwise the consequences might have been disastrous. It was made in the year 1900; the maximum authorised pressure was 40 atmospheres, and the apparatus had been tested to a pressure of 120 atmospheres. The dimensions are given in Fig. 2.

It is not possible to say at what pressure this digester exploded. The temperature had certainly reached 240° C. The lower part was heavily worn internally, as shown in Fig. 2; the thickness was reduced from 130mm. (5 $\frac{1}{8}$ in.) to 87mm. (3 $\frac{3}{8}$ in.), a maximum wear of 43mm. (1 $\frac{3}{4}$ in.). Notwithstanding this fact, which was known to the society, the latter felt justified in allowing the apparatus to continue in service, since on the basis of a 40-atmosphere pressure the stresses in actual service were much below the normal ones. The explosion must have been due to other internal forces much above

the working pressure, this being confirmed by the circumstance that the crack remained open in the cold state and when the piece was under no pressure, there being, in other words, a permanent deformation.

Inspection showed that the bottom part of the apparatus was covered by a 20mm. ($\frac{3}{4}$ in.) layer of chalky deposit, which must have greatly hindered the uniform transmission of heat. The temperature of the walls must have risen up gradually, and it is well known that grey cast-iron when overheated loses all its resistiveness; growth, following repeated heating and cooling in the ordinary way, also comes in, quite apart from all consideration of overheating. This question of growth of cast irons we may add, has been frequently dealt with by the members of the Iron and Steel Institute, and we may recall a very interesting paper on the subject by Professor H. C. H. Carpenter, F.R.S., read before the Institute at the autumn meeting of 1909. Judging from the report, the society appears to be acquainted with Professor Carpenter's work in regard to this phenomenon.

Some experts, the report further states, may claim that the crack formed is the consequence of tensile stresses due to contraction and not to elongation of the metal. The report adds that it cannot say in what way the molecules become displaced, but that it can safely compare the occurrence with what takes place in the case of a grate bar, which curves out until it breaks at the part submitted to the highest tension; in the same way, the bottom of the apparatus lengthened out, or tended to lengthen out, downwards until fracture occurred.

Test specimens were taken, as shown in Figs. 2 and 3. Specimens having 200mm. (7 $\frac{7}{8}$ in.) between supports gave the following figures of resistance to bending in tons per square centimetre:—

No. 1	2.56
No. 2	2.86
No. 5	2.86
No. 6	3.14

Two specimens gave the following percentage analyses:—

	Bottom No. 5.	Flange No. 1.
Silicon	1.32	1.31
Manganese	0.42	0.42
Phosphorus	1.01	0.99
Sulphur	0.102	0.101
Total carbon	3.32	3.25
Graphite content	3.26	3.14

The Swiss Federal stipulations concerning the tests of steel bridges require that the material should withstand a bending test of 2.80 tons per square centimetre. It will be seen that the test specimen from the flange was the only one not to give this figure. There is no remark to make in regard to the chemical analyses, apart from the high percentage of phosphorus. The bottom contained 0.12 per cent more graphite carbon than the flange; this rise probably took place during the period of service, for the micrographs of the ends of the specimens 3 and 4, which are reproduced in the report, show that there occurred a modification in the texture of the metal. In both instances the texture is very different from that of normal grey cast iron. The micro-sections prove that the material had long been exposed to high temperatures. It is not possible to say what temperature the flange was subjected to, presumably from 200° to 300° C., whilst the bottom end was probably heated up to 500° C.

The report concludes by advocating casting the autoclaves standing, the gate being over the flange and not over the bottom, for it is most important that the bottom be perfectly sound. It was not possible to determine in what way the vessel which failed was cast.—“Engineering.”

OBITUARY.—We regret to announce the death of the chairman of the British Empire Producers' Organisation (Sir Duncan C. Baillie, K.C.S.I., at Glenquich Lodge, Amulee, on August 30, in his 63rd year.—Mr. Edwin O. Sachs, F.R.S.E., F.R.G.S., died in London yesterday after a long illness in his 50th year. Educated at University College School, London, Mr. Sachs travelled extensively, and made a special study of the practical side of fire protection. In 1897 Mr. Sachs founded the British Fire Prevention Committee, and was responsible for the establishment, two years later, of the first fire-testing station in Europe. He also acted as vice-president of the International Fire Exhibition at Earl's Court, and organised the first Fire Prevention Congress which met in London in 1903. During the war he served as Commissioner of the Special Fire Survey Force, which he himself organised, and as member of the Home Office Departmental Committee on Celluloid Dangers.

SCIENTIFIC AND INDUSTRIAL RESEARCH.

PRIVY COUNCIL COMMITTEE'S ANNUAL REPORT.

(Continued from page 252.)

Oxygen Research.

In May of last year the Advisory Council's Committee on Mine-rescue Apparatus called their attention to the desirability of certain researches being undertaken into oxygen apparatus and the use of oxygen, but the Council understood that several Departments of Government were making investigations into these and allied subjects, though there was no means of knowing the exact scope of their activities. Since the Council are always unwilling to initiate research which appears to fall within the province of other Departments, they approached Sir Arthur Duckham, the chairman of the War Priorities Committee of the War Cabinet, with the suggestion that some means of co-ordinating the work already in hand might be useful. They assured him that they should not recommend the Privy Council to make any provision for research in connection with oxygen until it was clear that no overlapping would result from their action. They were warmly supported in this policy by the Medical Research Committee. Sir Arthur Duckham thereupon summoned a conference of all the Departments concerned, and in July, 1918, an Oxygen Uses Co-ordination Committee was established under the War Priorities Committee for the purpose of associating together those directing oxygen research for the Government. The committee thus constituted was placed under the chairmanship of Professor Jocelyn Thorpe, a member of the Advisory Council. It had no spending powers, and could only recommend a suitable line of action to the Department or body directly concerned. It received reports of the progress of the several researches being carried on, and discussed them with a view, in the first place, to the definition of the particular problems and, in the second, to their rapid solution. Treatises and memoranda were prepared by members and consultants on particular aspects of the work, and certain experiments and tests were recommended and carried out. One of the first recommendations of the committee was an inquiry into light cylinders for the transport of oxygen and other gases to be undertaken by this Department. An account of this work is given below.

In January last the War Priorities Committee ceased to exist, and at their request, with the concurrence of all concerned, the Oxygen Uses Co-ordination Committee was transferred to the Department of Scientific and Industrial Research, and placed in charge of a large part of the researches hitherto conducted by the various Departments of War. The title of the committee was accordingly altered to the Oxygen Research Committee, and an allocation of £5,100. was made for the purposes of their work during the current financial year. The therapeutic uses of oxygen, shown by recent practice to be capable of very great extension, are being actively investigated by the Medical Research Committee in close co-operation with the Oxygen Research Committee. The study of improved containers and cylinders, of gauges and general appliances, of different systems of oxygen production, and of aircraft and industrial uses, falls, on the other hand, to this Department. The development of the methods of holding and transporting liquid oxygen is a matter in which the Oxygen Research Committee are co-operating with the Air Ministry, War Office, and Mine Rescue Apparatus Research Committee, particularly with regard to the use of oxygen for airmen at high altitudes, and for the treatment of patients in hospitals and of casualties in wartime and in mines. The committee have also been giving attention to the uses of oxygen for industrial purposes, and many data have been collected with a view to inviting in due course the co-operation of commercial firms in research work.

Gas Cylinders Research.

An interesting development of the work of this committee has been the establishment of the Gas Cylinders Committee, under the chairmanship of Professor J. C. McLennan, O.B.E., F.R.S. The membership includes the Hon. Sir Charles Parsons, K.C.B., F.R.S., Professor C. V. Boys, F.R.S., Major A. Cooper-Key, C.B., who represents the Home Office, Professor J. F. Thorpe, C.B.E., F.R.S., and representatives of the Admiralty and the Ministry of Munitions, together with Professor H. C. H. Carpenter, F.R.S., president of the Institute of Metals, and other prominent metallurgical experts. An allocation of £1,000. has been approved to cover the work of this committee during the financial year ending March, 1920.

The incentive to the formation of this committee was the desire of the Home Office experts, through the Oxygen Research Committee, that the whole question of the manufacture and transport of cylinders used for compressed gases should be investigated, with a view to amending the present specification of materials of which cylinders must be made in order to comply with the railway regulations. It was suggested that this specification (which was legalised as the result of the findings of the Departmental Committee on the Manufacture of Compressed Gas Cylinders in 1896) was now out of date, in view of the progress which had been made during the last twenty years in steel manufacture and treatment, and that the regulation therefore compelled the employment of an unnecessarily heavy type of cylinder. It was thought possible that a lighter cylinder possessing the necessary factor of safety might be produced. During the war a number of light high-tension steel cylinders for oxygen for airmen had been made to an Air Ministry specification; and these, at the instigation of the Oxygen Research Committee, were thoroughly tested and examined mechanically and metallurgically by the National Physical Laboratory. The Gas Cylinders Committee took up this work, and, on the basis of the reports made by the National Physical Laboratory, are continuing the research with a view to evolving a suitable specification. It is not yet possible to forecast whether the committee will be successful in its efforts; but should this be the case, the advantage to the public should be very great. Oxygen, carbonic acid gas, and other gases are being applied to an ever-increasing variety of purposes, and a saving in the weight of the cylinders would produce considerable economy both in transport and in handling.

Lubricants and Lubrication.

Early in 1917 the Standing Committee on Engineering appointed a committee to report on the field of research in lubricants and lubrication, to give an analysis of the problems involved and to prepare a scheme of research. The committee have had monthly meetings throughout the year under review, and have continued not only their classification of existing research, but also their activities in connection with the experimental work at the National Physical Laboratory initiated with the Advisory Council's concurrence last year. The tests on different kinds of oil in the Lanchester worm-gear have been extended. Valuable results have been obtained and detailed reports prepared indicating the relative values of various lubricants under extremely high pressures. Every oil tested has also been examined and its physical properties determined, so that full particulars are available for comparison.

A new apparatus has been designed by Dr. Stanton and Mr. Hyde at the National Physical Laboratory for testing the change in viscosity of oils and other liquids with change in pressure. The first results of these experiments on different kinds of oil used in commerce have been obtained, and a report classifying them has been prepared. These are remarkable, and provide valuable data not previously available.

Mr. Deely, a member of the committee, has designed a friction or oil-testing machine suitable for comparing both different oils and different surfaces. This apparatus has been constructed and sent to the National Physical Laboratory, and tests will shortly be made with it.

The committee is preparing at the present time a brochure on solid lubricants, such as graphite, steatite, talc, etc., containing references to these substances in colloidal form and their lubricating value used alone, or as an admixture to oils. It is hoped that this brochure will be ready for publication shortly.

The work on the bibliography of research in lubricants is nearly completed. It will contain references to, and a classified index of, all work hitherto done and published in connection with lubricants and lubrication problems. It is hoped that this also will shortly be ready for publication.

The chairman is about to prepare the final report of the committee on the terms of reference submitted to it in 1917. and this report, complete with appendices containing detailed reports of the work carried out by the committee and at the National Physical Laboratory, together with the bibliography and the brochures, will be presented in the autumn of this year. It will also contain a critical survey of the state of knowledge on the problems under consideration by the committee, as well as recommendations as to future research work necessary. It is hoped that this report, together with the bibliography, will be a useful work of reference for engineers and others inquiring into such matters.

(To be continued.)

CORRESPONDENCE.

*, We do not hold ourselves responsible for the opinions expressed by our correspondents.

Zinc Oxide.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—We note that under this heading you refer to a letter from a Mr. Alexander J. McConnell published in *The Times*. Immediately we saw this letter we wrote both Mr. McConnell and the editor of *The Times*, as per enclosed copies. As we have received no reply from him, we enclose copy of a further letter we have addressed to *The Times* to-day.—Yours, etc.,

KEELING & WALKER, LTD.

London, September 5, 1919.

September 1, 1919.

The Editor, *The Times*,

Printing House Square, E.C.

Sir,—We have noticed a letter on "Zinc Oxide" from a Mr. A. J. McConnell to you in your issue of the 30th August. We have addressed a letter to Mr. McConnell as per enclosed copy, as it would be extremely interesting to know in what way zinc oxides manufactured by ourselves and other British manufacturers are so much inferior to the imported zinc oxide.—Yours, etc.,

KEELING & WALKER, LTD.

September 1, 1919.

Alexander J. McConnell, Esq.,

Isthmian Club, Picadilly, W. 1.

Sir,—We have seen your letter of the 29th ult. re Zinc Oxide in *The Times*, and we note with surprise your statement re the difficulty of obtaining a high-grade zinc oxide made in this country. If you care to let us have particulars of what is required, we do not for a moment doubt that we can offer you a zinc oxide equal to anything which can be imported from abroad.—Yours, etc.,

KEELING & WALKER LTD.

September, 5, 1919.

The Editor, *The Times*,

Printing House Square, E.C.

Re ZINC OXIDE.

Sir,—I thought it might interest you to know that so far we have received no reply from our letter addressed to Mr. McConnell, copy of which we sent you on September 1. It, therefore, would appear that Mr. McConnell's British Manufacturer is not really so anxious to obtain a pure zinc oxide, as it would seem from the letter which you published.—Yours, etc.,

KEELING & WALKER, LTD.

Chemists at Gretna Factory.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—I can quite understand the chemists at Gretna factory being discontented. The following is my brief and bitter experience of the Ministry of Munitions.

I gave up a good post in Canada, sold up my home, paid the passage for my wife and family, to accept a position under the Ministry of Munitions at £175 a year (hardly "profiteering?") "Steelworks chemists and chemical engineers preferred," was stated in their letter to me, and as I have had 13 years' experience of steelworks, I naturally thought I had been accepted for such duties.

On arrival in London I was sent to Gretna. I filled up a form for married quarters, and in the meantime lived in a hostel and paid for my wife's and family's apartments, board, etc., elsewhere.

My work was lifting bags of guncotton from trolleys into the N/G washhouse when filled with N/G lifting them back again; washing floors, etc. I suffer from asthma (which I mentioned when applying for the post, no objection being made.) After two months, being off work ill for 1½ days, the Ministry's doctor forbade me to work again in that part of the factory. I was sent to the main laboratory, and a few days after, at the end of the month, was given one month's notice, afterwards altered to three as per the original agreement.

The result of my returning to England under the Ministry of Munitions was, that I found myself considerably out of pocket, and also out of a situation.

I believe a large number of Australian chemists came over and arranged for their wives to follow later. This was then

found to be impossible, and I should imagine that unless salaries were raised considerably after I was discharged, all these chemists would be considerably out of pocket. At the time I worked at Gretna and was drawing money out of the bank to supplement my income, lead burners were being paid large wages by the Ministry of Munitions.

Many of the chemists at Gretna will no doubt have an idea of my identity if I sign myself,—Yours, etc.,

MULDOON, N.5.W.

Leeds, September 3, 1919.

Import Restrictions

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—I notice complaints in some quarters that the restriction of the import of fine chemicals has forced up prices against the consumer, and the case of salicylic acid and salicylates is referred to as proof of the contention. May I be allowed to point out that just prior to the restriction, English makers of these particular products were obliged to sell at below their cost of production in order to compete with foreign salicylic acid and salicylates "dumped" into this country and offered for sale at prices lower than those ruling in the country of origin. One of the chief objects my company has had in view in urging the restriction of the import of certain fine chemicals is to secure to the British manufacturer a reasonable margin of profit, and makers cannot be blamed if they now secure this with the object of so establishing their business as to be in a position to compete with all comers when the import restriction is removed. Manufacturers know quite well that the unreasonable forcing up of prices against the consumer would only result in again opening the market to the foreign competitor. Manufacturer and consumer—wholesaler and retailer—surely realise that import restrictions are only a means to an end—viz., the ultimate establishment of important "key" industries within the British Isles on such a scale as to be proof against all foreign competition. If this commendable object is kept constantly in mind it should not be difficult to adjust business to meet the new conditions without inflicting hardship in any quarter.—Yours, etc.,

RALPH J. PUGH.

London, September 5, 1919.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

THE heavy demand upon a coal production, which although larger than it was a fortnight ago is still 13 per cent. to 15 per cent. below what it was in June, has made it impossible for the coke ovens to get all the coal they require. Round coal is having to be crushed to meet the needs of the 380 by-product ovens which are in operation, and even then difficulty is being experienced in keeping the plants working at within two-thirds of their capacity. What the position would be if additional furnaces on ordinary iron were put into blast it is difficult to say. Unfortunately, no change has occurred in the iron trade to render it necessary to obtain a bigger make of coke. The likelihood at present is rather that the make of ordinary iron will be decreased, and that of low phosphorus iron, for which East Coast coke is more suitable, increased. Any diminution of output of ordinary iron is not, however, probable for some months to come, the rail trade, it is stated, having booked sufficient business to maintain the present scale of operations until the end of the year.

The condition of the by-product market does not call for any greater make than is now being secured. It is true that benzol is all being absorbed, and that the entire output of sulphate of ammonia is being marketed, but the same cannot be said of other by-products.

Pitch is in strong demand, but there is not a ready absorption of the make in this district, and creosote is not moving away rapidly.

ZINC AND ZINC DUST PRICES.—The price of Australian high-grade zinc dust (88/92% metallic zinc) is unchanged at £68/£70. per ton c.i.f. U.K. The price of Australian electrolytic zinc (99/95% purity) is unaltered at £42. per ton f.o.b. Australia for direct shipment to New Zealand, India, South Africa, and the Far East.

ITEMS OF INTEREST.

IRON ORE IN NORTHERN QUEBEC.—Official reports just published indicate the existence of almost inexhaustible deposits of iron ore in the Ungava district of Northern Quebec.

GERMAN POTASH SUPPLIES.—*Reuter's* Berlin correspondent says it is reported that the German Government have undertaken to supply Great Britain with 22,000 tons of potash by the end of the present year.

GERMAN DYES FOR AMERICA.—The United States War Trade Board, according to *Reuter's* Washington correspondent, has issued an order allowing the importation of six months' supply of dyes from Germany for American manufacturers.

ENEMY PATENTS.—British Dyes, Ltd., have been granted licences to use twenty-nine patents belonging to the Badische Anilin und Soda Fabrik and Farbwerke vorm. Meister, Lucius, and Brüning. The Pure Russian Liquid Paraffin Co., Ltd., have been granted a licence to use Edeleanu's patent (11140/08) for the purification of paraffin.

TAR.—The Municipality of Bombay invite tenders for supply of 120,000 gals. of tar, 60,000 gals. to fulfil the requirements of the British Standard Specification No. 1, and 60,000 gals. to the British Standard Specification No. 2; to be delivered f.o.b. at an approved port. Forms of tender may be obtained at the offices of Sir John Wolfe Barry, Lyster and Partners, Dartmouth House, 2, Queen Anne's Gate, Westminster, London, S.W. 1. Tenders endorsed "Tender for Tar" must be addressed to the Consulting Engineers and Agents, as above, and delivered before noon on September 15.

MINISTRY OF MUNITIONS ORDERS.—By orders of the Ministry of Munitions the following orders were suspended as from August 1:—The Potassium Compounds Order, 1917, as modified by the Potassium Compounds (Partial Suspension) Order, 1919, the Optical Munitions Order, 1915, the Glass Control (Consolidated) Order, 1917, and the Glass Control (Consolidated) Amendment Order, 1918. It is also notified that the Ministry of Munitions revoke the Munitions (Ordering of Works) Regulations, 1916 and 1917. A similar notice is given by the Admiralty with reference to the Munitions (Ordering of Work in Admiralty Establishments) Regulations of last year.

QUININE CONTROL.—It is understood that Government control of quinine is being removed forthwith. This is satisfactory inasmuch as it will promote normal trade in the drug. A slight increase in price is inevitable, and it is learned that the Dutch Combine, which controls practically the whole world's supply of the drug, has decided to raise the price slightly. This is a natural consequence of the present scarcity of the drug, and the increased demand as against dwindling supplies and a reduced production. It may be said with authority that the Government control price during the war has not been representative of the actual economic conditions affecting the drug.

MANGANESE OUTPUT DECREASES.—Reports to United States Geological Survey covering the first three months of 1919 show that shipments of high-grade manganese ore were 23,937 tons, against 75,465 tons during the last quarter of 1918 and 305,869 tons during the entire year. Shipments of ore containing 10 to 35 p.c. manganese were 35,516 tons, against 320,455 tons during last quarter of 1918, and 913,163 tons during the year. Montana led in shipments of high-grade ore, Nevada in low-grade shipments. Decrease in shipments is due to unwillingness of ferro-manganese makers to increase their rather large stocks of ore, especially as there is now only a small market for the alloy.

THE HÖCHST DYEWORCS.—A recent number of the *Frankfurter Zeitung* announced that, in consequence of coal shortage, a large part of the Höchst dyeworks would be shut down, presumably only for a short time. The pharmaceutical and a few other important departments will continue working. The 1918 report of the Höchst Dyeworks states that so far it has not been possible to restore the production of peace goods to any great extent. In the course of the work of renovating the peace plants it became evident, moreover, that they had suffered so severely—partly from their long inactivity, partly from their war uses—that the amounts hitherto reserved would not suffice for the depreciations effected, and that additional funds must be provided. Apart from the new plant required, the restoration of the business to a peace footing will require considerable expenditure.

MANURES.—The Poplar Board of Guardians invite tenders for artificial manures, as under, for delivery to Laidon Station, Midland Railway (L.T. and S.), for use at the branch workhouse: Ten tons of basic slag; four tons sulphate of ammonia; three tons superphosphate. Forms of tender to be obtained from Mr. H. E. Dennis, clerk, Guardians' Offices, Poplar, E. 14, are to be returned by 6.30 p.m. on September 17.

METALLURGICAL RESEARCH.—Mr. John Dixon Brunton, of Musselburgh, has given £1,000. to the Applied Science Department of the Sheffield University, the income from the sum to be expended yearly on a medal and premium for the best metallurgical research work done at the university during the year. At a meeting at the university a letter was read from Mr. Brunton explaining that he took this course because of the great advantage he had derived from the knowledge he gained at the university when a student there.

CELLULOID BLAZE. A consignment of four tons of celluloid was destroyed by fire on a steam wagon and trailer at Warrington on Wednesday. Messrs. J. Blake and Co., carriers, Manchester and Liverpool, were transferring the celluloid, which was in a number of wooden cases, from the Liverpool docks to the Rexine Co., Ltd., Hyde. When the wagon was passing over Bank Quay railway bridge the steerer heard a woman scream, and on looking round saw a fierce flame rising from the boxes. The flames rose to a height of nearly 50 feet, and they were so fierce that an electric trolley wire was burned through and fell to the ground.

THREATENED STRIKE IN SCOTTISH SHALE OIL TRADE.—On the invitation of the Anglo-Persian Oil Company, representatives of the Federation of Scottish Oil Workers met in conference at the offices of the company, Britannia House, London, on Monday, with representatives of the Anglo-Persian Oil Company, the Scottish Mineral Oil Association, Ministry of Labour and Petroleum Executive, for the purpose of discussing the points of difference at present existing between the companies and the men, and to make an endeavour to reach such a conclusion as will avoid the stoppage of work which is threatened. The decision of the Federation to cease work in support of their demands for a shorter working week and consequent revision of rates, affects fully 9,000 workers.

PERSONAL.—Mr. Forsyth J. Wilson, D.Sc., Ph.D., F.I.C. (late captain and chemical adviser to the 11th Army Corps), who has been appointed Professor of Inorganic and Analytical Chemistry in the Glasgow Royal Technical College, had a distinguished career at Edinburgh University, and was engaged in extensive research in connection with war operations.—Mr. H. Cooper, M.P.S., Ph.C., who was until recently at the Wellcome Chemical Works, Dartford, is shortly proceeding to India to take up an appointment in the works of Messrs. Smith, Stanistreet and Co., Ltd., manufacturing chemists, Calcutta.—Mr. Isidor M. Heilbron, D.S.O., D.Sc., Ph.D., F.I.C. (late lieutenant-colonel and a senior staff officer in the Salonica Forces), who has been appointed Professor of Organic Chemistry in the Glasgow Royal Technical College, was a distinguished student of the college. He was awarded the James Young Exhibition. As a result of his work at the university there his Exhibition was continued, and he took the degree of Ph.D. He became a member of the Technical College Staff in 1908, and is the author of several works on technical subjects.

REFRACTORY MATERIALS.—The fundamental importance of a knowledge of the properties of the refractory materials used in high-temperature furnaces has been for some time recognised by the United States Government, and the Bureau of Standards has for the last two or three years been engaged in researches on the subject. The quartz or ganister bricks used for furnace work in the States are made mainly in Pennsylvania from crushed and ground quartzite rock. About 2.5 per cent. of lime is added, and the mixture moulded in steel moulds, dried, and burnt in kilns at 2500-3000° F. The best procedure to be followed in these processes, and the effects of variations of the procedure, are discussed in Technologic Paper No. 116 of the Bureau by Mr. D. W. Ross, and the effects of repeated burnings on the constitution and micro-structure of the bricks by Messrs. H. Insley and A. A. Klein in No. 124. It appears that the quartz is converted on heating into cristobalite and tridymite, which are both of lower density. Unless this conversion is completed during the original burning, the resulting brick will expand on further heating, with serious results to the structures of which they form a part.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Nitrate of soda.—Although showing, as we expected, some increase of 56,000 tons, last month's shipments from Chili were kept within a very narrow compass through the continued dearth of available tonnage. The sailing vessels formerly regularly employed in the trade are now carrying grain and other foodstuffs more urgently required in Europe than nitrate of soda, many of them having, moreover, been sunk during the war by German submarines, which paid particular attention to the valuable cargoes used by the Allies in the manufacture of explosives. So scarce are steamers at the present time that up to 240s. per ton has been paid to French Atlantic ports (Bordeaux, Nantes, La Rochelle), with 10s. more to Marseilles; and it may be imagined what prices the Chilean fertiliser will stand at to the Continental consumer. The output on the West coast fell further away in August to 107,000 tons, only a small number of oficinas remaining at work, and so enormous is the accumulation of stocks that instead of the anticipated increase of production in the autumn months a decrease will be seen unless the congestion can soon be relieved through the arrival of numerous ships. A sale of 6,000 tons of "refined" nitrate is reported at 9s. 3d. to 9s. 6d. per quintal, f.o.b., for October delivery, as also second-hand parcels of ordinary quality at 8s. 11d.; but the deadlock between the Producers' Association and those outside it still continues, and the former threatens to put prices down to 8s. per quintal if the latter do not join the "convenio!" *Brutum fulmen.* Nitrate is likely enough to fall of its own deadweight to that figure without the producers cutting off their nose to spite their face, there being already sellers at 9s. According to the Board of Trade returns, no nitrate of soda was imported into the United Kingdom last month.

Alsatian Potash Sales: Norway a Buyer.—France Alsatian potash is the subject of a proposed contract between France and Norway, which the French Government is quite prepared, it is said, to facilitate. France is in a position, and is willing, to deliver 40,000 tons of potash to Norway during the next five years, and it is suggested that the goods should be shipped at Belgian ports. Prices named are: For Sylvinites, 14 per cent., 70 francs per ton at the mine; rich sylvinites up to 20 per cent., 100 francs per ton; chloride of potassium of 50 per cent., 375 francs per ton; and for transport and packing, the cost at Antwerp, it is calculated, would make 20 francs per ton. The Alsatian Potash Sales Bureau has published the quantities of deliveries of potash in France in the first six months of the current year—namely: Sylvinites (kainit), 12-16 per cent., 77,055 tons; sylvinites, rich, 20-22 per cent., 40,048 tons and chloride of potassium, 50-60 per cent., 14,428 tons; total, 131,531 tons, equal to 27,543 tons pure anhydrous potash. It ought to be remembered in view of the foregoing figures that in the year 1913 the French consumption did not exceed 35,000 tons of pure anhydrous potash.

Sulphate of Ammonia.—Business in this material is moving with a fair amount of activity, but it is clear that consumers are not particularly pleased with the advances in price. They can perhaps have nothing to say about the justice of the increase, but in some cases the fear is expressed that intensive cultivation may be retarded by the upward movement. Everyone will agree that a bigger production of foodstuffs is part and parcel of the great national need of altogether increased production of the moment. At the same time, the multitude of augmented costs affects the sulphate men as it affects other sections of traders, and higher prices must result. Across the Atlantic the tendency is also upwards. There most of the producers are sold up for September, and seem to have all the business they can handle for October. The inquiry for export is steady, but the regular operators are in no position to take care of this business for immediate delivery. Small stocks are reported to be available in second hands.

Potash.—Trade is moving quietly in connection with the new potash supplies, and further announcements indicate that more of this fertiliser is being arranged for transport to Great Britain. Since August 7 authorisation has been given in the United States for the importation into that country of potash produced or manufactured in Germany. Potash may now be sent into the U.S.A. from every foreign source except Hungary and those parts of Russia which are under the control of the Bolsheviks, irrespective of the fact that it may have been produced in Germany.

Other Fertilisers.—These are pretty generally in small request, with perhaps the special exception of basic slag. In that particular section consumers are again complaining of delayed deliveries. The position of this material has been greatly improved by the experience of recent years, and agriculturists are strongly enamoured of it. Miscellaneous fertilisers do not provide much to comment upon this week. Bone-meals remain in very short supply, and blood and tankage are very little more than nominal markets. Fish meal is in a fair trade where any supplies are offered, and is said to command prices like 27s. 6d. for ammonia and 2s. 6d. for phosphates. Even 30s. for ammonia has been mentioned.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

Business in tinplate is getting quite lively, and inquiries are numerous from foreign countries. More mills are being prepared for restarting, and the outlook is now brighter than at any time during the last five years. Manufacturers have still some difficulty in getting sufficient leading workers to man their mills. The independent chairman of the arbitration board has given his award in favour of the employees, who will receive their full demand of the 12½ per cent asked for. Export arrangements are much better and shipments to foreign ports are steadily increasing. The home requirements are also strong and pre-war customers are now reopening negotiations for regular supplies of tinplates.

Big developments are expected in the patent fuel business, for months past chemists have been engaged on research foreign demand for briquettes proves absolutely that this work in some of the best-known factories, and the increasing kind of trade has a great future before it. Mr. W. R. Llewellyn is endeavouring to amalgamate several large colliery and steel manufacturing firms, and the deal involves something like £7,000,000. He has now controlling interest in the Graigola Fuel Works, and since he undertook an active interest in this plant, it has been enlarged and extensions are still going on in order to double the pre-war yield of briquettes made by this company, and should this "big deal" come off the patent fuel trade will be largely extended in order to meet foreign customers' requirements. The principal shipments for the week went to Buenos Ayres, St. Nazaire, Rouen, and Bayonne. Coke orders are now more numerous, and the yields of by-products are consequently increasing. Shipments of coke have during the week been made at Newport for Massamedest, St. Malo, Dieppe, Barcelona, and Treport, and quantities left Cardiff for West Indies and Lisbon. In a few weeks' time there will be several new batteries of by-product ovens working, and as far as South Wales is concerned, the production of sulphate of ammonia, benzol, etc., is to be considerably increased during the next 12 months. There are between 200 and 300 new ovens nearing completion, and it is safe to say that should Mr. W. R. Llewellyn be successful in his negotiations for securing the leading collieries in one huge concern, many more ovens will speedily be erected.

A parcel of phosphoric ore from St. Nazaire arrived at Newport, and some 2,250 tons of iron pyrites have been discharged at Swansea docks.

COMING EVENTS.

Institute of Metals.—The annual autumn meeting will be held in Sheffield on **Wednesday and Thursday, September 24 and 25.**

Iron and Steel Institute.—Autumn meeting at the House of the Institution of Civil Engineers on **Thursday and Friday, September 18 and 19.**

James Watt Centenary.—Celebrations at Birmingham on **Tuesday, Wednesday, and Thursday, September 16, 17, and 18.**

DEPARTMENT OF OVERSEAS TRADE.—The statement which has appeared in the Press as to the control of the Department of Overseas Trade is unauthorised and incorrect. The Department remains under the joint control of the Foreign Office and the Board of Trade, and any arrangements made as regards housing will not affect this joint control.

NEW COMPANIES.

Colour Oxidising Company, Ltd.—Private company. Capital £8,000., £1. shares (2,000 10 per cent. cumulative preference). Electro platers, smiths, chemists, etc. Solicitors: H. S. Holt, 6, Gray's Inn Square, W.C.

Consolidated Mines of Cornwall, Ltd.—Private company. Capital £66,000., £1. shares (33,000 7 per cent. cumulative preference). Object: Agreement with H. Van den Bergh. Winners and workers of and prospectors for china, mica, and fire-clays. Registered office: 8, Hart Street, Mark Lane, E.C.

Dick's Asbestos Company, Ltd.—Private company. Capital £100,000., £1. shares. Objects: To take over the business of Dick's Asbestos Company carried on by W. F. Dick at 47, Fenchurch Street, E.C. Manufacturers of and dealers in asbestos, fibres, non-conducting coverings, asbestos bricks and cements, engine and pump packings, etc. Office: 47, Fenchurch Street, E.C. 3.

Castleary Fireclay Company, Ltd.—Capital £100,000., £1. shares. Miners of and dealers in clay, fireclay, coal, limestone, ganister, etc., and to enter into an agreement with the Silling Company, and James Winning, the liquidator thereof. Solicitor: J. J. McMurdo, 10, Bank Street, Airdrie.

Indo-Burma Oilfields, Ltd.—Private company. Capital £100., £1. shares. Objects: To prospect for, acquire, develop, and deal in oil-bearing lands and properties in India, Burma, the Malay States and elsewhere, etc. Solicitors: Guedalla, Jacobson and Spyer, Austin Friars House, E.C.

Selby Chemical Company, Ltd.—Private company. Capital £55,000., £1. shares. Registered office: Holme Works, Holme Lane, Selby, E. Yorks.

Southdown Chemical Company, Ltd.—Private company. Capital £60,000., £1. shares. Objects: To take over the business of chemical manufacturers, makers of dyes, intermediates, drugs, lubricants, and other substances, etc. Registered office: Beaufort Road, Birkenhead.

Welsh Tinplate and Metal Stamping Company, Ltd.—Private company. Capital £500,000., £1. shares. Objects: To take over the business of the Welsh Tinplate and Metal Stamping Company, Ltd. (incorporated in 1911), manufacturers of and dealers in iron, steel, terne and black plates, etc. Registered office: Cambrian Works, Sea Side, Llanelli.

Apex Trinidad Oil Fields, Ltd.—Capital £200,000., £1. shares. Objects: To acquire petroleum and other properties in Trinidad or elsewhere, to refine and deal in petroleum and other mineral oils, and to enter into an agreement with the Anglo-French Exploration Company, Ltd., and the British Borneo Petroleum Syndicate, Ltd. Solicitors: Holmes, Son and Pott, Capel House, E.C.

LEGAL INTELLIGENCE.

Alleged Theft of Government Metal.

Alleged extensive thefts of Government metal during the war formed the subject of a charge at Bow Street Police Court, when Albert Evan Watcott, a general dealer, of Pyrland Road, Canonbury, was charged with obtaining by false pretences forty tons of scrap lead, the property of the Ministry of Munitions, and valued at £1,291. 12s. 8d. Detective-sergeant Aldridge gave formal evidence of the arrest of the defendant on Monday night, and stated that when charged Watcott said "Righto." The officer asked for a remand. The magistrate granted the application, and fixed bail in one surety of £400.

Commonwealth Oil Corporation.

In the Vacation Court, London, Mr. Justice Greer had before him an application in reference to the Commonwealth Oil Corporation, Ltd., a considerable number of debentures in which are held in Scotland. Counsel asked that the company's petition for the sanction of the Court to a scheme of arrangement should be in the paper for hearing on September 17. There was an important agreement dependent upon the sanction of the Court being obtained during the present month. As evidence had to come from Scotland, it might be that it would be necessary to ask for further indulgence on the 17th. His Lordship, in acceding to the application, mentioned that he himself was a debenture holder and had a general knowledge of the scheme, of which he had formed a very favourable opinion. In the circumstances, he did not know whether he could deal with the matter, but for the present he would preserve an open mind. The parties, however, should be informed that he was a debenture holder.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

Australia.

A Sydney firm, with useful connections throughout Australia, desire to obtain the representation, for Australia, of United Kingdom manufacturers of dry colours for cement and magnesite work. The inquiring firm would prefer to do business solely on a commission basis. (Reference No. 554.)

Canada.

A Canadian firm desire the addresses of United Kingdom firms prepared to import high-grade felspar, phosphate, and pyrites.

Egypt.

A United Kingdom firm, whose business organiser for the Egyptian district has returned to this country on a short visit, wish to get into touch, with a view to obtaining agencies, with first-class United Kingdom manufacturers of dyes and soap. (Reference No. 559.)

South Africa.

A Johannesburg agent desires to secure the representation of United Kingdom firms for soaps. (Reference No. 563.)

Belgium.

An old-established firm in Liège desire to purchase, and would also accept agency, with dépôt, for the following articles: Chemical products, drugs, pharmaceutical products, and soap. (Reference No. 565.)

A wholesale firm in Verviers, with twenty-two years' experience in the textile industry, wish to obtain an agency, with dépôt, for chemicals for dyeing and glue for the manufacture of tissues. The firm claim to have a good clientele in Liège and Brussels. (Reference No. 566.)

Brazil.

A partner of a firm of general commission agents in Pernambuco (a British subject), who has had several years' experience in Brazil, is at present in this country, and desires to obtain agencies, on a commission basis, for varnishes, chemicals, drugs, and dyes. He is also desirous of exporting native produce from Pernambuco, including oil seeds and fibres and carnauba wax. (Reference No. 585.)

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Acetylene Equipment Company, Ltd.—Meeting of creditors, Palmerston House, Old Broad Street, E.C., September 10.

Adams British Oil Company, Ltd., Deptford, S.E.—R. H. Johnston ceased to act as receiver August 16.

Fleetwood Fish Meal Company, Ltd.—Resolved August 6, confirmed August 22: That the company be wound up. W. F. Harris, Bank Chambers, Parliament Street, Hull, chartered accountant, liquidator. Meeting of creditors at Hodgson, Harris and Co.'s, Bank Chambers, London Street, Fleetwood, September 6. Claims to liquidator by October 18.

Hay's Waterproof Glue and New Patent Enamel and Varnish Company, Ltd.—Meeting of creditors, 24A, Commercial Road, Portsmouth, September 17, at 11 a.m.

Premier Oil and Pipe Line Company, Ltd.—Meeting of creditors, Institute of Chartered Accountants, Moorgate Place, E.C., September 15, at 11 a.m.

Welsh Tinplate and Metal Stamping Company, Ltd., Llanelli.—Resolved August 1, confirmed August 22: That it is desirable to reconstruct the company, and having regard to the agreement, dated June 4, 1919, and made between Danl. Williams on behalf of himself and all the other holders of shares in the company of the one part, and Thos. Jones Randell on behalf of the new company therein mentioned of the other part (being an agreement providing, amongst other things, for the exchange of shares in this company for shares in the said new company), and to the fact that such agreement has been duly ratified, that this company be wound up. D. Williams, Box House, Llanelli, and others, liquidators, who are authorised to consent to the registration of a new company, to be named the Welsh Tinplate and Metal Stamping Company, Ltd.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

The specifications of the following applications are not printed by the Patent Office until the complete specifications have been accepted.

September 1st to 6th (inclusive).

Catalysts. Adam, M. A.; and Legg, D. A. 21,667.
 Manufacture of Coarsely Crystalline Substances from Solutions. Aktieselskapet de Norske Saltverker. 21,684.
 Explosives. Atlas Powder Co. 21,438.
 Apparatus for Aerating Liquids. Bailey, A.G. 21,787.
 Artificial Silk. Bouffe, G. F. J. 21,643.
 Bleaching Process. Brierley, S. 21,720.
 Soap Manufacture. Brown, R. 21,786.
 Treatment of Explosives for Use as Fuel. Crittall, R. G., and Musgrave, J. L. 21,647.
 Composite Fuel. Day, T.; Johnston, J.; and Summerfield, W. 21,960.
 Cellulose Derivatives. Dreyfus, H. 21,474, 21,661, 21,662, and 21,773.
 Aromatic Derivatives. Dreyfus, H. 21,554.
 Apparatus for Splitting Up or Getting Pitch, etc. Guldner, G. W. 21,505.
 Fixation of Atmospheric Nitrogen. Island, J. S. 21,690.
 Concentration of Bituminous Coal by Flotation. Jackson, W. J. Mellersh (Metals Recovery Co.). 21,573.
 Process of Evaporating Liquids. Krause, G. A. 21,553.
 Roasting and Sintering Ores, etc. Lloyd, R. L. 21,812.
 Electric Furnaces. Luca, D. de. 21,582.
 Treatment of Sulphide Ores. Mackay, P.A. 21,819.
 Flotation Separation of Mineral Substances. Nevett, R. D.; Palmer, T. H.; and Seale, H. V. 21,608.
 Production of Liquid Ammonia. Norsk Hydro-Elektrisk Kvælstofaktieselskab. 21,447.
 Separating Fats, Oils, etc., from Waste Waters. Poumier, R. 21,451.
 Still for Distilling Tar, Pitch, Benzol, Naphtha, Ammonia, and Carboic Acid. Sinfeld Bros.; Sinfeld, D.; and Sinfeld, H. 21,483.
 Drying-plants. Zimmermann, O. 21,881.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 6d. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.

1916.

Obtaining of Nitrogen Compound from the Nitrogen of the Atmosphere. Montgomery, C. J.; and Royston, E. R. 9,210.
 131,609

1918.

Process for Purifying Liquids. Riiland, A. 5,016. 121,452
 Tubular Evaporating and Cooling Apparatus. Barbet et Fils et Cie. E. 5,232. 114,838
 Production of Glycols. Weizmann, C.; and Bainbridge, E. G. 9,131. 131,628
 Production of Dopes. Barr, A. J. A. W.; and Lazell, H. 10,862. 131,641
 Manufacture of Liquid Nitrogen Peroxide and Nitric Acid. W. R.; and Nobel's Explosives Co. 10,869. 131,642
 Incendiary Material. Chanard, A. 10,884. 131,644
 Production of Solutions of Cellulose Acetates and Methods of Joining Articles Made of Cellulose Acetate. Gilmour, R.; and Dunville and Co., W. 10,949. 131,647
 Manufacture of Dopes having a Basis of Acetate of Cellulose. Dreyfus, H. 12,085. 131,669
 Ferrotitanium. Blackwell, H. A. 12,364. 131,675
 Production of Esters. Grolea, J.; and Weyler, J. L. 12,455. 131,678
 Manufacture of Hydrogen, Nitrogen, and Carbon Dioxide. Harger, J.; and Lever Brothers. 12,565. 131,384
 Recovery of Zinc by Electro-deposition. Electrolytic Zinc Co. of Australasia Proprietary, Ltd. 13,369. 131,702
 Removing Paint and Rust from Iron, Steel, and Copper. Marino, Q. 13,665. 131,709
 Evaporating-apparatus. Thunholm, K. L. E. 13,760. 118,635
 Regenerative Furnaces of the Soaking Pit Type. Stein et Cie, C. M. 14,177. 120,039
 Roasting and Refining Impure Tin. Bolitho, H. 14,233. 131,743
 Compound of Lime and Bromine. Arthur, J. S.; and Kilby, L. G. 14,661. 131,750
 Devices for Discharging Predetermined Quantities of Glass from Glass Furnaces. British Thomson-Houston Co.; and Gray, J. 14,862. 131,756
 Electric Furnaces. British Thomson-Houston Co. (General Electric Co.). 15,320. 131,767
 Chrome Liquors and Salts. Blockey, J. R.; and Walker and Sons, W. 15,786. 131,772
 Centrifugal Pumps. Frame, W. J. 17,074. 131,781
 Alkaline Electric Accumulators. Cave, A. M. 17,338. 121,118
 Means for Extracting Water from Washed Coal. Burnett, C. 17,874. 131,788
 Pressplates for Oil-Expressing Presses. French, A. W. 18,789. 131,798
 Complete Separation of Liquor and Remelted Syrup Directly in Remelting Centrifugal Machines. Lemoine, J. L. 12,244. 131,860
 Device for Use with Furnaces for Enabling the Progress of Combustion to be Ascertained. Hintze, J. G. W. 18,686. 131,864

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Portland Cement. W. S. Akerman, Burnham, Somersetshire. British Patent, 128,750, of 1918.

Raw merl composed of limestone and shales, with which may be mixed a portion of the fuel used in the second part of the process, is heated in a closed chamber so as to drive off carbonic acid and other gases and the oil and tar constituents, and then introduced into a vitrifying chamber of the kiln, the oil, etc., driven off from the calcining-chamber being recovered, and the gases from the calcining-chamber being collected for further use, such as for supplementing the heat for vitrifying, or to assist the waste heat from the vitrifying-kiln which passes to the walls of the calcining-chamber. The calcining-chamber may be in the form of a pipe, which is situated in a continuous kiln of the type having oscillatory shafts, and is provided with means for excluding the air while the contents are automatically discharged by gravitation.

Antimonious Oxide. E. F. Morris, Roby, near Liverpool. British Patent, 128,818, of 1918.

To assist the aerial oxidation of antimony to antimonious oxide, the presence of a small proportion of one or more of the following substances, sulphur, sulphide of arsenic, and sulphide of antimony, is maintained throughout the process.

Tin Salts. A. W. Gregory, Greenwich, London. British Patent, 128,833, of 1918.

Tinned scrap is treated with a hot solution of ammonium polysulphide prepared by adding an ammonium salt such as the sulphate to sodium polysulphide. Caustic soda may also be present in the solution. The saturated solution is treated to recover the tin as sulphide by neutralising, for instance, with nitre cake, sulphuric acid, hydrochloric acid, or sulphur dioxide.

Paints. J. F. Bottomley, Brighouse, Yorkshire. British Patent, 128,402, of 1918.

A priming or paint for surfaces of concrete, cement, artificial stone, etc., comprises a solution of zinc sulphate and a small proportion of an azo-compound such as the sodium salt of *p*-sulpho-benzene-azo- β -naphthol. Azo-compounds suitable are those which are suitable for acid dyes on wool and similar fibres.

Amines. W. Rintoul, J. Thomas, and Nobel's Explosives Company, Ardeer Factory, Stevenston, Ayrshire. British Patent, 128,372, of 1918.

Tertiary amines are separated from admixed secondary amines by treating the mixture at low temperatures with phosgene to convert the secondary amine into the corresponding urea chloride; if the tertiary amine is present in excess, the separation can be effected in one stage, the mixture of urea chloride, tertiary amine hydrochloride, and free tertiary base being washed with dilute hydrochloric acid which extracts all the tertiary base as hydrochloride, which is then decomposed by alkali. If the secondary base is in excess in the mixture, either free tertiary base is added until there is excess thereof and the resulting mixture is treated as above, or the initial mixture is treated with half the equivalent of phosgene; the product is washed with water to extract the hydrochlorides of the bases, and the bases precipitated from this solution by alkali, and subjected again to the action of phosgene, and the operations repeated until the separation is complete. The secondary bases are regenerated from the urea chlorides by hydrolysis by boiling with dilute acid or water. Examples are given of the treatment of crude diethylaniline containing monoethylaniline and of a mixture of mono- and di-ethyl-*o*-toluidine.

Manufacture of Ammonia. I. W. Cederberg, H. M. Backstrom; and G. A. Kyhlberger, Stockholm, Sweden. British Patent, 127,063, of 1918.

Ammonia is produced at temperatures below 400° C. and at pressures exceeding 250 atmospheres by treating mixtures of nitrogen and hydrogen with a catalytic agent consisting of one or more of the following: metallic copper, silver, gold, zinc, cadmium, mercury, gallium, indium, thallium, germanium, tin, lead, arsenic, antimony, or bismuth, or a compound of such a metal which is capable of reacting with nitrogen or hydrogen or both to form ammonia, or a compound which under the conditions of the catalytic operation yields either the metal or a compound such as those indicated

above. Examples of catalysts mentioned are copper asbestos, zinc powder, mercury nitride-bromide, 2HgBr_2 , Hg_3N_2 , copper hydride, zinc amide, copper ferrocyanide. In an example, copper oxide is precipitated on asbestos and heated in ammonia at 325°C ., which produces cuprous nitride. This is used as a catalyst at a pressure of 680 atmospheres.

Dyes.—A. G. Perkin, Leeds. British Patents, 126,764 and 126,765, of 1918.

N-Dihydro, 1': 2: 2': 1'-anthraquinoneazine is obtained by fusing 2-aminanthraquinone with caustic potash and a sugar, such as glucose, cane sugar, or lactose.

Dibenzanthrone is prepared by fusing benzanthrone with caustic potash in the presence of a sugar, such as glucose, cane sugar, or lactose.

Distilling and Carbonising Pitch. F. M. Perkin and Nitrogen Products and Carbide Company, London. British Patent, 129,091, of 1918.

The destructive distillation and carbonisation of pitch is carried out in two or more stages at different temperatures, the first in metal stills or retorts at a temperature not exceeding 600°C ., and another at a temperature of from 900° to 1000°C ., the coke or carbon finally obtained being particularly suitable for the manufacture of carbon electrodes. Fig. 1 shows an iron still or retort *b* for the first stage of the

process arranged above ordinary horizontal retorts *a*. The pitch may be run into the still *b* at *c*, and this may be heated by the waste heat from the high-temperature retorts below; *f* are catch-pots through which the gases from the outlet pipes *g*, *e* pass for collecting the oil, etc. Fig. 2 shows an arrangement in which horizontal gas retorts are used for both stages, the low-temperature retorts *b* being provided with iron trays *b'* to receive the pitch.

Lactic Acid. A. P. H. Desborough, Holton Heath; J. Reilly, St. Ambrose, Parkstone; and A. C. Thaysen, Dorsetshire. British Patent, 128,687, of 1918.

Lactic acid is formed by fermenting sugars, such as maltose, which may be obtained by the action of malt or moulds upon cereals, chestnuts, acorns, etc., dextrose, saccharose, mannite, raffinose, and arabinose, with a new type of lactic-acid producing organism—viz., *bacterium volutans*,—which is found in sour mash, maize or other cereal meal, soil, carrots, and parsnips, and is identified by the size and by the production of volutine, which can be detected microscopically by staining with polychrome methylene blue solution. The acidity developed by the fermentation is reduced by repeated addition of preferably sterilised alkali, alkaline-earth compounds such as calcium carbonate or oxide, or other oxides, hydroxides, or carbonates such as zinc or ammonium compounds. The lactates may be separated by evaporation and crystallisation, and other lactates obtained by double decomposition. The crude lactates may be washed with small quantities of water, and the wash-liquors worked up for separation of volatile fatty acids, such as acetic or butyric, which are formed during the fermentation. The lactates may be decomposed with sulphuric or other acid, and the lactic acid separated by extraction with butyl or isobutyl alcohol. Volatile fatty acids may be separated from the lactic acid by distillation. The lactic acid may be purified by converting it into lactide by heating in a current of air or otherwise, separating the lactide by distillation under reduced pressure, purifying it by crystallisation, and reconvert it into lactic acid by heating with

lactic acid solution, or into lactates by treatment with metal hydroxides. Solutions for fermentation may be obtained by treating brewers', distillers', or other mash which have been spoilt by entry of foreign organisms by saccharifying with malt if necessary, and boiling.

Phenols. South Metropolitan Gas Company and E. V. Evans, London. British Patent, 129,002, of 1917.

In the manufacture of aromatic hydroxy compounds by fusing aromatic sulphonic acid with caustic alkali, the alkali sulphite resulting from the fusion is electrolysed to give caustic alkali for further use in the fusion, and sulphur dioxides, which is either converted into sulphuric acid and used in the sulphonation, or is used to convert the alkali phenolate into free phenol. Or, instead of removing the alkali sulphite, the whole mass of alkali phenolate, alkali sulphite, and excess alkali is dissolved in water and electrolysed, giving free phenol.

Varnishes. British Aeroplane Varnish Company, London; and J. G. Ward, Felling-on-Tyne, Durham. British Patent, 129,033, of 1917.

The viscosity of varnishes consisting of solutions of celluloid nitrocellulose, or other cellulose ester in organic solvents such as ketones or esters, to which may be added diluents such as benzole, benzene homologues, or alcohols, or softening agents such as oils or gums, is preserved by addition of small quantities of an organic polybasic acid such as citric or tartaric acid. The amount of acid may be only sufficient to neutralise the alkalinity; or if the solution is neutral or acid, a salt of the acid may be added.

Derivatives of Benzene, Toluene, and Naphthalene. H. N. Morris and Co., H. N. Morris, and W. J. Sable, Manchester. British Patent, 129,074, of 1918.

Di- and tri-nitro derivatives of benzene, toluene, and naphthalene, and ketonic derivatives such as benzophenone, are treated with a silicious earth such as fuller's earth or kieselguhr to decolorise them and remove impurities such as

iron, etc., which affect the crystallisation. The substance, melted or in solution, is mixed with the earth in a steam-jacketed pan *A* by a rotating stirrer *B* which is surrounded by an open cylinder *C* having slots *e* in its base. The liquid is run through a steam-jacketed filter *F* to crystallising troughs.

REPORTS OF COMPANIES.

Yorkshire Dyeware and Chemical Company.

The trading profits of the Yorkshire Dyeware and Chemical Company for the year ended June 30 were £59,216, and £6,451. was brought forward. Debenture interest absorbed £3,591, and a final dividend of 5 per cent. and a bonus of 25 per cent. are proposed, making 35 per cent. for the twelve months, adding £15,000. to the reserve, and £20,000. to the extensions fund, and carrying forward £8,701. The board recommend that the share capital be raised to £150,000. by the capitalisation of £75,000. of the reserve fund, and that one new 15s. share be added to every similar share now held. Mr. J. E. Bedford and Mr. G. H. Clemons (directors) and Messrs. Armitage and Norton (auditors), ask re-election. The company's trading profits for 1917-18 were £46,351., for 1916-17, £57,956., and for 1915-16, £54,002., and distributions for each period were similar to those proposed for the past year. Twelve months ago £25,000. was reserved, in 1917, £30,000., and in 1916 £29,000.

British Gas Light.

Report for half-year ended June 30 last states that, after providing for debenture interest, the net revenue amounted to £15,470., which with balance brought forward makes available total of £66,845. The directors recommend dividend at rate of 10 per cent. p.a., less tax, payable October 3, leaving £46,895. to be carried forward. Earnings of past half-year are disappointing and at most of company's stations very inadequate. It will be necessary to further advance price of gas at those stations at which the maximum price authorised by Parliament has not already been reached. Meeting, 11, George Yard, Lombard Street, E.C., September 24, noon.

Calico Printers' Association.

Owing to fact that directors have still been unable to arrive at a settlement with the Inland Revenue authorities in respect of the company's liabilities for excess-profits duty, and are not yet in a position to submit accounts for year ended June 30. In these circumstances the directors propose to adjourn the meeting so far as presentation of report and accounts is concerned, but to transact the other business of

an ordinary general meeting. Directors recommend dividend at rate of five per cent. p.a. on preference for half-year ended June 30 last, and dividend of 5 per cent. for year on ordinary, both less tax, payable September 30 to shareholders registered September 15. Meeting, Memorial Hall, Albert Square, Manchester, September 17, at noon.

Cordoba Copper.

The directors announce that the negotiations referred to at the annual general meeting in April last have been brought to a successful conclusion, the whole of the company's property in Spain having been disposed of, with the consent of the Board of Trade, for a sum of 1,000,000 pesetas, payable in cash. The sale has been completed and the purchase money received. The total assets of the company are now represented by a sum of approximately £70,000., which is invested in Government securities. With regard to future policy, the Board will submit their recommendations to the shareholders at the earliest possible date.

DIVIDENDS.

MUNTZ'S METAL.—Interim dividend for half-year at rate of 5 per cent. per annum (6d. per share), less tax, on ordinary, payable October 1. The same dividend was paid last year.

HARRISONS AND CROSFIELD.—The directors have declared a dividend on the cumulative preference shares at the rate of 6 per cent. per annum for the three months ending September 30, 1919, less tax at 6s. in the £. Warrants will be posted September 29.

MANDLEBERG (J.) AND Co.—Interim dividend for half-year at rate of 10 per cent. per annum (1s. per share), less tax, on ordinary, payable September 15. The same dividend was paid last year.

OIL PRODUCTION IN CANADA.—An oil-refining plant is to be erected at Regina, Saskatchewan, involving an expenditure of £200,000. While it will be impossible to complete construction this year, it is hoped that sufficient work will be done to enable the company to proceed with the distillation of crude oil, and further additions will be made as business demands. The crude oil will reach Regina from the Wyoming oil fields, and a modern refinery will be erected to meet the rapidly expanding business in Saskatchewan.

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS

WEDNESDAY.

Benzole: London 90%, 1s. 10d. to 2s.; North, 1s. 8d. to 1s. 9d.; 50%, 1s. 10d.; North, 1s. 8d. to 1s. 9d. naked. Carbolie acid, crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 9d. to 9½d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch 77s. 6d. to 80s.; East Coast, 67s. 6d. to 75s., f.o.b.; West Coast, 60s. to 65s., f.a.s. Solvent naphtha, naked, London, 90-190%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-160%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthaline, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 6d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid, 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b., other ports. Sulphate of ammonia; home trade, £19. 10s. per ton; basis 24½%. Nitrate of soda, £22. to £22. 10s.

FERTILISER MATERIALS.

LIVERPOOL, THURSDAY.

Nitrate of soda.—The market for this material is unchanged. The quotation on spot for 95/96% quality being £20. 2s. 6d. per ton, net cash, f.o.r. prompt delivery. Best Indian Bone Meal.—For shipment is without alteration, the nearest value being £15. 5s. per ton, net cash, ex-ship, Liverpool. September/November shipment. On spot holders require £15. per ton, net cash, for 4½% and 45% quality. Mineral Phosphates.—There is no alteration to report in this market, and values are at present only nominal. Dried Blood.—This article is very scarce, the nearest value being about 30s. per unit of ammonia per ton.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £100. 10s. to £100. 15s. cash; £101. to £101. 5s. three months; electrolytic, £109. to £120. Tin: Standard, £282. to £283. cash; £276. to £276. 10s. three months; Straits, £284.; English, £279. Lead: Soft foreign, £25. 2s. 6d.; English, £26. 5s. Spelter, £40; hard, £30. to £31. Antimony, English regulus, 90%, £45. Aluminium £150. Nickel £205. delivered, packages extra. Quicksilver £23. 10s. to £24. Bismuth 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

There is a continued steady demand for all heavy chemicals, both on home and export account, and values all round are well maintained with only few exceptions. Makers' quotations for caustic soda are unchanged viz., 76% £24., 74% £23. 5s., and 70% £22. per ton. Refined bicarbonate of soda easy at £7. per ton, bags f.o.r. Bleaching powder is only moving slowly, but price is unaltered. Soda crystals, bags, £4. 2s. 6d., rails. Chlorates are slow of sale—soda at 6½d. and potash 1s. per lb. Makers' quotations for bichromates are without change. Sales of sulphate of copper are still on the small side, and price is weak at £42. per ton, f.o.b. Cornish hypo of soda firmly held for £16. per ton on rails. Phosphate of soda £26. per ton. Saltcake 60s. per ton, carriage paid. Recovered rock sulphur steady at £17. on rails. Supplies of arsenic are still difficult to obtain, and price is nominally £60. per ton. Yellow prussiate of potash is firm at 1s. 9d. per lb. Soda has advanced during the week to 8d. per lb., and has an upward tendency. Carbonate of potash 80/85% £95. per ton. Lead salts are in fairly good request. English white at £83. and brown £70. Nitrate £56. per ton. Acetic acid unchanged at recent rates. Acetate of soda quiet at £52. per ton. English brown acetate of lime scarce and dearer

at £11. 10s. per ton delivered. Grey £17. 10s. per ton. Borax continues scarce and £52. per ton is asked for spot parcels. All tin, zinc, and ammonia salts are moving off steadily. Green copperas in only small request and price easy at £4. 10s. per ton.

SWANSEA MARKET REPORT.

WEDNESDAY.

There were plenty of buyers for tinplates, and prices ruled very firm for all grades. Standard boxes were quoted at 36s. per box basis, f.o.b. Copper has a tendency to recede, buyers displaying caution in transactions, which ruled at £100. 5s. per ton for prompt and £101. 5s. three months. Tin was dearer at £282. cash and £275. three months. Lead remains steady, with only small orders passing at £25. 2s. 6d. per ton for Spanish and £26. 5s. for English. Spelter rather quiet and easier at £40. 5s. per ton over next six weeks. Zinc sheets, English, quoted at £64. per ton, and American £65., f.o.b. at New York. Silver 61d. per ounce. Quicksilver £23. 10s. per bottle. Nickel £205. per ton, delivered London, or equal. Aluminium £150. Antimony, English regulus, 90%, £42. Pitch scarce at 55s. per ton at ship. Sulphate of ammonia steady, United Kingdom prices for current month £19. 10s., next month £20. 10s. Nitrate of soda quiet but steady at 21s. 6d. per cwt., in bags. Seed oils remain scarce, with cottonseed edible quoted at 110s., and ordinary 95s., per cwt. Rape Oil dull. English refined, 119s. per cwt. in barrels. Palm oil quiet and dull. Lagos £90. 5s., softs £90., Benin £86., and hards £83. per ton. Petroleum in moderate supply and firm at 1s. 6½d. to 1s. 7½d. per gallon, in 40gal. barrels. Turpentine £6. 10s. per cwt. net. Copperas quiet at £4. per ton, delivered. Oxalic acid 1s. 2½d. per pound. Arsenic has assumed a better tone and in better request at £54. 10s. per ton for white powdered, in bags, f.o.b. Sulphate of copper, small trading at £42. 10s., in casks, less 5%, f.o.b.

TURPENTINE MARKET REPORT.

Messrs. James Watt & Son, Ltd., of 101, Leadenhall Street, London, E.C.3, report that the stocks of turpentine on September 6 were: American, 32,299 barrels, compared with 6,155 barrels at the corresponding date of 1918; French 44 barrels (14 barrels); and Spanish, 674 barrels (1,674 barrels). Deliveries during the week ended September 6 were 1,553 barrels, against 98 barrels last year, and since January 1 49,484 barrels, compared with 17,290 barrels in 1918. The price on Saturday last was 129s. per cwt., compared with 120s. at the corresponding date of last year. October-December delivery was quoted at 130s. 6d. and January-April (1920) 133s.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

A fairly active inquiry for chemicals has been experienced since the beginning of the week, the demand, both from the export branch and from the home branch of the trade showing an improvement. Supplies of some of the more important articles have become very short, so that prices continue high, and the situation is inducing freer offerings of supplies from outside sources. Bleaching powder has been quieter, with prices, £14. 10s. to £15. per ton, free on rail or conveyance, in buyers' packages, for home trade uses; and £17. per ton, for export. Chloride of calcium has been in fair demand and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has been in good request and has been more inquired for on export account. Quotations are: £24. per ton for 76%; £22. per ton for 70 to 72%, and £19. per ton for 60 to 62%. Nitrate of soda has moved more freely, and the price is slightly higher. It is £21. to £22. per ton. Saltcake has been in very fair demand and is £6. 10s. per ton, in casks, f.o.b. Soda crystals have been steadily called for and are £5. per ton, in 2cwt. bags, f.o.r. at works. Bicarbonate of soda has been in fairly active demand and is £7. 5s. to £10. per ton, according to terms of delivery. Borax continues to be well inquired for, and supplies available for early deliveries have been very small. This has led to offerings of American borax but the prices quoted for it have been too high for much business to be done in this product. Prices for English borax may be given as; ordinary, £42. per ton; powdered, £44. per ton, in bags. Ammonia alkali has been in good request, and is £6. to £6. 5s. per ton, f.o.r. at works. Hyposulphite has been in moderate demand and is £17. per ton for ordinary, and £22. per ton for pea crystals. Sulphite of sodium has again been but little in request and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals, in 1cwt.

kegs. Bichromate of soda has been in very fair demand and is 9d. per lb. Phosphate of soda has been rather more in request and is £25. per ton. Sulphide of sodium has had a moderate inquiry and is £20. per ton in casks and £22. per ton in drums. Chlorate of potash has been quieter and is 1s. 1d. to 1s. 2d. per lb. Permanganate of potash has met with a steady inquiry and is 3s. 3d. to 3s. 6d. per lb. Sulphate of potash has moved but slowly and is £40. per ton. Carbonate of potash has been in very fair demand and is £90. to £95. per ton for 80 to 85%. Caustic potash has sold rather freely and is £110. to £120. per ton. Nitrate of potash has been more in request and is £55. to £60. per ton for refined, and £40. per ton for ordinary. Canadian potashes have had a very limited sale. Montreal first quality are £210. to £220. per ton and second quality, £190. to £210. per ton. Bichromate of potash has been in quietly steady demand, and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been in somewhat better request and is 1s. 9d. to 1s. 10d. per lb. Salammoniac has sold a little more readily, and is £80. per ton for lump, £75. per ton for seconds and £5. per ton extra for ground. Sulphate of ammonia has been rather more inquired for, and is £19. 10s. per ton, for September; £20. 10s. for October; £20. 15s. for November; £21. for December; £21. 7s. 6d. for January, 1920; £21. 15s. for February; and £22. per ton for March to May, 1920. Carbonate of ammonia has met with a fair inquiry and is 6½d. per lb. Muriate has been very quiet and the price is easier. It may be given as £45. to £50. per ton, according to quality. Magnesia has sold more readily. Carbonate is £3. per cwt. and sulphate, £10. to £16. per ton, according to grade. Alum continues to meet with a rather active inquiry, and has been in very short supply for early deliveries. It is £18. 10s. per ton for the home trade, and £18. 10s. to £19. 10s. per ton for export. Aluminoferric has been inactive and is £8. 10s. to £12. per ton according to quality. Sulphate of alumina has been in moderate request and is £12. to £17. per ton, according to grade. Sulphur has been in good request, and in very light supply. English kinds are: Flowers, £32. per ton; roll, £28. per ton, and rock, £22. per ton, in bags, f.o.r. Sicilian grades are: flowers, £28. per ton; roll, £22. 10s. per ton, and rock, £17. 15s. per ton. Cream of tartar has been in fairly active demand and is £11. 10s. to £11. 15s. per cwt. Tartaric acid has had a quietly steady sale but has been in very light supply. It is 3s. 2d. to 3s. 3d. per lb. Boracic acid has sold with some freedom and is £72. per ton for crystals, and £74. per ton for powdered. Oxalic acid has sold more readily and is 1s. 2d. to 1s. 3d. per lb. according to time of delivery, the price being easier, for forward dates. Citric acid has been rather more in request and is 4s. 4d. per lb. White acetate of lead has been but little in request and the price has eased. It is £83. to £85. per ton. Arsenic has had a slow sale, but the price has again risen. White powdered is £55. per ton. Sulphate of copper has met with a somewhat freer inquiry, and export prices are a little lower. Quotations are: £44. per ton for farm uses in the United Kingdom, and £42. per ton, in bags, and £43. per ton in casks; less 5 per cent., f.o.b. at Liverpool.

TYNE CHEMICAL REPORT.

TUESDAY.

There is no change to report; the demand for bleaching powder and caustic soda, home consumption, continues good; for export the inquiry improves. Soda crystals are in strong request at £5. per ton, 2cwt. bags. Sulphur continues scarce and firm. The following prices are per ton, net: Bleaching powder, softs, £15.; do., hards, £15.; caustic soda, 74-77%, £23. 5s.; do., 70%, £22.; do., 60%, £20.; recovered sulphur, 2cwt. bags, £23.; hyposulphite of soda, 5-7cwt. casks, £19.; do., 1cwt. kegs, £25.; sulphite of soda, 5-7cwt. casks, £12.; do., 1cwt. kegs, £20.; silicate of soda, 75° Tw., £9. 12s. 6d.; do., 100° Tw., £10.; do., 140° Tw., £10.; soda crystals, 2cwt. bags, £5.; sulphate of soda (saltcake), in bulk, £3. 10s.; pure white sulphate of alumina, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18.; do., refined concentrated solid, 60-62%, £25.; hydrate of barium, crystals, £56.

COALS.—The demand for all classes of coal is insistent, and apparent supplies continue far below ordinary requirements. Steam and bunker coals are in very strong request. All Scandinavian countries are pressing orders on the market. To-day's prices: Best Northumbrian steam, 95s. to 100s. per ton; second qualities, 85s. to 90s.; Northumbrian small coals, 75s. to 80s.; seconds, 70s. to 72s. 6d.; best Durham gas coals, 80s. to 85s.; seconds, 65s. to 75s.; Durham bunker coals, 70s.

to 80s.; seconds, 65s.; foundry coke, 90s. to 100s.; gas coke, 95s. to 100s.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Wednesday.

There is being maintained a fairly steady demand for all classes of chemicals as far as this market is concerned, and, generally speaking, the tone of the market is firm. Prices do not show any material alteration, and the most noticeable change since last report is in the case of arsenic, which is now selling at £56. per ton, as against £55. previously. Big deals are more in the picture than for some time past, but some buyers are still pursuing a very cautious policy. Current quotations are: Arsenic, £56. per ton, net, Glasgow; bicarbonate of soda, £8. 15s. and £10. per ton for 6-8 casks and 1cwt. kegs, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags, and borax crystals, £39. for 2cwt. bags, carriage paid; caustic soda, white, 70-72%, £24. per ton, net, Glasgow; chlorate of potash, 1s. 1d. per lb., net, Glasgow; chlorate of soda, £3. 4s. per cwt. net, Glasgow; citric

acid, 4s. 4d. per lb. 5% Glasgow; cream of tartar 98% £11. 5s. per cwt., net, Glasgow; paraffin wax U.K. deliveries 125°, 6½d. to 6¼d.; 121-3°, 5½d. to 5¼d.; 118-20°, 5½d.; 110-120°, 4d. to 4½d.; and 98-102°, 4d. to 4½d.; salammioniac, £80. and £75. per ton, net, any port, for first and second lump respectively; salammioniac crystals, £85. per ton, net, Glasgow; saltpetre, £3. 4s. net, Glasgow; tartaric acid, 3s. 1d. per lb., 5% Glasgow.

In the sea oils there is still a wider selection of the different oils available, and prices remain without change of any kind. The demand for the different varieties of whale oils has been well maintained, and pale has been selling at 102s., brown at 76s., and black at 74s. Yellow, however, is still minus any quotation. Newfoundland cod continues to change hands at 79s.; pale seal when on offer stands at 96s.; and Menhaden has many inquiries at 86s.

In the coal trade the position is quite unchanged. All classes of fuel are in strong demand by local consumers, and industrial works generally seem to be absorbing as much as ever. On the export side trade continues limited, and, more or less, the whole output is being kept for home purposes.

IMPORTS OF CHEMICAL PRODUCTS

AT THE PRINCIPAL PORTS OF THE UNITED KINGDOM.

BRISTOL.

Publication of Official Returns

bay, 14 kgs., £498.; Constanti-
nople, 1 ck., £17.; Madras, 5
kg., £33.; Salonika, 1 ck., £35.;
Shanghai, 1 kg., £11.

LEAD CARBONATE—

Rio de Janeiro, 2 cs., £20.

LEAD OXIDE—

Salonika, 1 ck., £21.

MAGNESIA (CALCINED)—

Paris, 20 cks., £102.; Rio de
Janeiro, 2 cs., £18.; Sao Paulo,
1 cs., £11.

MAGNESIUM CARBONATE—

Buenos Ayres, 4 cs., £15.;
Malaga, 2 cs., £15.; Shanghai,
2 cs., £8.; Seville, 2 cs., £8.

MAGNESIUM CITRATE—

Barbados, 1 cs., £5.; Constanti-
nople, 2 cs., £11.; East London,
1 cs., £5.; Rio de Janeiro, 1 ck.,
£17.; Valparaiso, 1 cs., £10.

MAGNESIUM SALICYLATE—

Pelotas, 1 cs. (pt.), £5.

MAGNESIUM SULPHATE—

Barbados, 5 c., £13.; Bombay,
8 c., £18.; Durban, 4 c., £9.;
East London, 4 c., £6.; Fre-
mantle, 2 t. 8 c., £87.; Kilindini,
8 c., £13.; Mauritius, 5 c., £7.;
Pt. Elizabeth, 4 c., £7.; Seville,
4 c., £7.; Wangarmi, 11 c., £23.

MANGANESE BORATE—

Genoa, 3 cks., £85.

MANGANESE DIOXIDE—

Constantinople, 2 cks., £20.

MANGANESE OXIDE—

Lisbon, 8 cks., £140.

MERCURY ARSENATE—

Christiania, 5 cs., £370.

MERCURY CHLORIDE—

Amsterdam, 1 cs. (pt.), £20.

MERCURY OXYCYANIDE—

New York, 2 cs., £88.

MERCURY OXIDE—

Amsterdam, 10 cs., £842.

MERCURY PIRCHLORIDE—

Calcutta, 1 cs., £6.

MERCURY SUBCHLORIDE—

Madras, 1 cs., £100.

METAPHOSPHORIC ACID—

Paris, 10 cs., £190.

METHYL SALICYLATE—

Italy, 8 drms., £64.

NITRIC ACID—

Alexandria, 3 c., £19.; Tripoli,
2 c., £9.

OXALIC ACID—

Valparaiso, 1 cs. (pt.), £6.

PARAFFIN WAX—

Genoa, 60 t. 14 c.

PARAFORMALDEHYDE—

Amsterdam, 1 cs., £73.

PHOSPHORIC ACID—

Melbourne, 22 cs., 1 t., £207.;
Sydney, 7 cs., £37.; Wellington,
10 c., £80.

PHOSPHORUS—

Soerabaya, 1 cs., £10.

PLUMBAGO—

Dunedin, 11 c.; Gothenburg,
2 c.

POTASSIUM ACETATE—

Canton, 12 cs. (pt.), £6.; Rio
de Janeiro, 5 cks. (pt.), £17.

POTASSIUM BICHROMATE—

Antwerp, 54 cks., £2,950.; Con-
stantinople, 1 cs., £39.; Ham-
burg, 6 cks., £490.; Rio de
Janeiro, 9 cks. (pt.), £7.;
Salonika, 1 ck., £39.; Swatow,
2 cks., £31.

POTASSIUM BROMIDE—

Calcutta, 2 cs., £45.

POTASSIUM CARBONATE—

Alexandria, 1 ck., £6.; Antwerp,
24 cs., £121.; Rio de Janeiro,
18 cs. (pt.), £32.

POTASSIUM CHLORATE—

Cyprus, 1 c., £13.

POTASSIUM CHROMATE—

Canton, 12 cs. (pt.), £12.

POTASSIUM CYANIDE—

Canton, 6 c., £155.; Rio de
Janeiro, 1 c., £26.

POTASSIUM HYDROXIDE—

Shanghai, 3 cs. (pt.), £9.

POTASSIUM IODIDE—

Alexandria, 1 cs. (pt.), £9.;
Beyrout, 7 cs. (pt.), £8.; Bang-
kok, 1 cs. (pt.), £48.; Durban,
1 cs. (pt.), £39.; Maceio, 1 ck.
(pt.), £39.; Madras, 5 cks., £450.;
Rio de Janeiro, 28 cks. (pt.),
£166.; Rio de Janeiro (F.), 2 cs.,
£164.

POTASSIUM PERMANGANATE—

Colombo, 1 kg., £21.; Melbourne,
3 cs., £58.; Rio de Janeiro, 22
cks. (pt.), £91.; Sao Paulo, 1 cs.,
£75.

POTASSIUM SULPHATE—

Canton, 1 c., £6.

POTASSIUM SULPHIDE—

Buenos Ayres, 1 cs., £77.; Rio
de Janeiro, 46 cks. (pt.), £117.;
Sao Paulo, 1 ck., £21.

PYROGALLIC ACID—

Bangkok, 1 ck. (pt.), £5.

QUININE—

Alexandretta, 125 ozs.; Alexandria, 585 ozs.; Amoy, 1,000 ozs.; Cyprus, 64 ozs.

SALICYLIC ACID—

Amsterdam, 1 ck., £28.; Antwerp, 1 ck., £17.; Batavia, 1 ck., £13.; Colombo, 1 cs. (pt.), £6.; Italy, 4 pkgs., £49.; New Plymouth, 1 cs., £10.

SALT—

Durban, 1 t.; Mombasa, 1 t.; Paramaribo, 1 t.; Sabang, 4 c.; Trinidad, 6 t.

SALTPETRE—

Axim, 5 c., £19.; Barcelona, 4 t., £200.; Batavia, 1 c., £5.; Buenos Ayres, 10 t., £580.; Canton, 1 c., £5.; Colombo, 4 c., £14.; Durban, 8 c., £30.; Pelotas, 10 c., £41.; Rio de Janeiro, 3 c., £17.; Rosario, 1 t. 19 c., £108.; Santander, 2 t. 4 c., £104.; Wellington, 4 t., £200.

SHEEP DIP—

Delagoa Bay, 10 c., £23.; Hastings, N.Z., 5 c., £8.; Pt. Elizabeth, 15 t. 6 c., £552.

SILVER NITRATE—

Hong Kong, 2 cs., £149.

SOAP—

Aden, 7 c.; Alexandria, 14 c.; Auckland, 9 c.; Antwerp, 387 t. 13 c.; Amsterdam, 7 c.; Archangel, 3 t. 3 c.; Ascension, 11 c.; Bombay, 17 t. 13 c.; Batavia, 2 t.; Boulogne, 107 t. 15 c.; Buenos Ayres, 1 c.; Calais, 3 c.; Cape Town, 6 c.; Calcutta, 17 c.; Channel Islands, 1 t. 10 c.; Cheribon, 2 c.; Christchurch, 3 c.; Cologne, 109 t. 1 c.; Colombo, 1 t. 4 c.; Constantinople, 9 t. 15 c.; Copenhagen, 48 t. 4 c.; Cyprus, 3 c.; Danzig, 7 t. 16 c.; Delagoa Bay, 1 c.; Demerara, 8 c.; Dunkirk, 6 t. 4 c.; Durban, 1 c.; East London, 1 c.; Genoa, 18 c.; Ghent, 2 t. 3 c.; Hong Kong, 4 c.; Karachi, 1 t. 14 c.; Kobe, 4 c.; Leghorn, 11 t. 10 c.; Lisbon, 1 c.; Montreal, 14 c.; Macassar, 7 c.; Mazagan, 19 t. 13 c.; Medan, 5 c.; Melbourne, 6 c.; New York, 1 t.; Paris, 1 t. 6 c.; Penang, 3 c.; Piraeus, 4 c.; Rio de Janeiro, 1 t.; Rostoff, 1 c.; Rotterdam, 5 t. 2 c.; St. Helena, 2 c.; Shanghai, 19 c.; Singapore, 1 t. 7 c.; Smyrna, 2 t. 1 c.; Soerabaya, 4 c.; Sydney, 4 c.; Suez, 8 c.; Vienna, 1 t.; Wellington, 3 c.; Yokohama, 1 c.

SODA CRYSTALS—

Rotterdam, 9 t. 14 c., £63.; Tripoli, 1 t., £5.

SODIUM & POTASSIUM TARTRATE—

Rio de Janeiro, 5 cks. (pt.), £17.

SODIUM ARSENITE—

Durban, 2 t. 1 c., £110.

SODIUM BENZOATE—

Athens (F.), 4 cs. (pt.), £7.; Calcutta, 1 cs., £21.; Calcutta (F.), 1 cs., £12.; Maceio (F.), 1 cs. (pt.), £8.

SODIUM BICARBONATE—

Antigua, 3 c., £5.; Batavia, 11 c., £12.; Bombay, 3 c., £10.; Buenos Ayres, 6 c., £16.; Demerara, 10 c., £6.; Fremantle, 1 t. 5 c., £15.; Lima, 10 c., £9.; Malaga, 4 c., £5.; Rotterdam, 10 t., £90.; Seville, 4 c., £5.; Smyrna (F.), 3 t. 6 c., £120.; Tripoli, 10 c., £5.

SODIUM BISULPHITE—

Antwerp, 1 t., £33.; Batavia, 7 t., £210.; Colombo, 40 drms., £56.

ODIUM CARBONATE—

Alexandria, 10 c., £26.; Batavia, 1 c., £5.

SODIUM CITRATE—

Calcutta, 1 cs. (pt.), £23.; Perth, 1 cs. (pt.), £7.

ODIUM CYANIDE—

Cape Town, 2 c., £15.

SODIUM GLYCEROPHOSPHATE—

Athens, 4 cs. (pt.), £5.; Amsterdam, 1 dr., £34.

SODIUM HYPOPHOSPHITE—

Constantinople, 6 cks., £250.; Genoa, 18 pkgs. (pt.), £44.

SODIUM HYPOSULPHITE—

Antwerp, 5 t., £105.; Bangkok, 12 pkgs. (pt.), £13.; Lisbon, 10 c., £15.; Rio de Janeiro, 4 c., £6.; Singapore, 20 kgs., £22.

SODIUM IODIDE—

Calcutta, 1 cs. (pt.), £12.; Beyrout, 7 cs. (pt.), £10.; Gothenburg, 1 cs., £34.

SODIUM NITRATE—

Gibraltar, 5 t., £117.; St. Kitts (F.), 8 t., £204.

SODIUM PRUSSATE—

Genoa, 2 t. 19 c., £200.; Kobe, 38 cks., £646.; New York, 60 t. 5 c., £4,436.; Osaka, 5 t. 3 c., £337.

SODIUM SALICYLATE—

Calcutta, 4 cs. (pt.), £10.; Colombo, 1 cs. (pt.), £8.; New Plymouth, 1 cs., £22.

SODIUM SULPHATE—

Antwerp, 1 t., £15.; Buenos Ayres, 3 t., £38.; Mauritius, 9 c., £8.

SODIUM SULPHITE—

Alexandria, 10 c., £31.; Batavia, 2 c., £7.; Brussels, 6 c., £9.; Shanghai, 1 t., £22.

SODIUM TARTRATE—

Amsterdam, 2 cks., £34.; Calcutta, 1 ck., £14.; Montreal, 10 c., £70.; New York, 5 t., £700.; Sydney, 10 cks., £70.

STEARINE—

Paris, 10 t.

SULPHATE OF QUININE—

Calcutta, 11,500 ozs.

SULPHUR—

Amsterdam, 2 c., £8.; Brussels, 17 c., £34.; Paris (F.), 10 t., £180.; Rouen (F.), 4 t., £90.

SULPHUR (FLOWERS)—

Paris, 1 t., £40.

SULPHURIC ACID—

Canton, 4 c., £20.; Madras, 2 c., £10.; Penang, 1 c., £14.; Rio de Janeiro, 6 c., £30.; Seconade, 520 t., £13,000.

SULPHUROUS ACID—

Ghent, 60 cks., £158.

SUPERPHOSPHATE OF LIME—

Gibraltar, 10 t., £97.

SUPERPHOSPHATES—

Channel Islands, 60 t., £390.; Cyprus, 70 t., £665.

TALLOW—

Nantes, 14 t. 13 c.; Rotterdam, 2 t. 13 c.

TANNIC ACID—

Bahia, 1 cs., £27.; Pelotas, 1 cs. (pt.), £21.; Sydney (F.), 2 cs., £41.

TARTARIC ACID—

Bahia, 1 c., £21.; Bombay (F.), 3 c., £59.; Cape Town, 2 c., £37.; Demerara, 1 c., £10.; Karachi (F.), 1 t. 4 c., £420.; Lima, 1 c., £19.; Lytleton, 15 c., £228.; Madras, 2 c., £19.; New York, 1 t. 10 c., £518.; New York (F.), 2 t. 10 c., £910.; Pt. Sudan, 1 c., £18.; Rio de Janeiro, 3 c., £68.; Suez, 1 c., £20.; Valparaiso, 1 c., £12.

THEOBROMINE—

Kobe (F.), 2 cs., £204.

WAX—

Antwerp, 3 t.; Christchurch, £7.

WHITE LEAD—

Antwerp, £643.; Batoum, £300.; Bombay, £483.; Bordeaux, £2,120.; Buenos Ayres, £823.; Calais, £474.; Dunkirk, £300.; East London, £115.; Ghent, £335.; Hong Kong, £136.; Karachi, £74.; Lytleton, £118.; Malta, £65.; Paris, £1,560.; Piraeus, £623.; Shanghai, £233.

ZINC OXIDE—

Madras, 2 cs., £40.

MANCHESTER.

Week ending September 3.

ALUM LUMP—

Alexandria, 69 brls. Tunis, 20 dbl. bgs. Turin, 25 brls.

ALUM AMMONIA—

Jaffa, 35 brls.

AMMONIUM CARBONATE—

Tunis, 5 cks.

AMMONIUM MURIATE—

Turin, 7 kgs.

ANILINE OIL—

Antwerp, 13 drms.

ANILINE SALT—

Beyrout, 32 cks. Tunis, 10 cks.

BORAX—

Beyrout, 5 cks.

BORIC ACID—

Beyrout, 1 ck.

COAL PRODUCTS (otherwise undes.)

Antwerp, 146 tes.

DYESTUFFS (otherwise undescribed)

Antwerp, 1 kg.

DYESTUFFS—

Aniline Colours

Tunis, 1 cs.

Sumac Extract

Alexandria, 5 kgs.

Turnerle

Turin, 26 bgs.

GLUE—

Limassol, 1 bg.

GLYCERINE—

Beyrout, 7 cs.

INDIGO—

Turin, 4 chts.

MAGNESIA (CALCINED)—

Tunis, 2 cs.

MAGNESITE—

Havre, 100 bgs.

OXALIC ACID—

Havre, 8 cks.

POTASSIUM CARBONATE—

Tunis, 1 cs.

RED LEAD—

Limassol, 1 kg.

Turin, 5 cks.

SALAMMONIAC—

Turin, 2 brls.

SALT—

Quebec, 2,400 sks.; St. Johns, 5,880 sks.

SOAP—

Alexandria, 1,601 cs.; Jaffa, 32 cs.; Malta, 316 cs.

SODIUM BICARBONATE—

Alexandria, 20 bgs.; Beyrout, 40 kgs.

SODIUM SULPHIDE—

Havre, 2 cks.

SULPHUR (ROLL)—

Limassol, 3 kgs.

TARTARIC ACID—

Limassol, 1 kg.

WAX—

Alexandria, 80 cs.

WHITE LEAD—

Turin, 10 kgs.

WOOD TAR—

Limassol, 1 brl.

MIDDLESBROUGH.

Week ending September 6.

ARIUM BINOXIDE—

Dieppe, 22 t. 14 c., £2,724.

ARIUM NITRATE—

Antwerp, 2 t., £100.

BENZIDINE BASE—

Dieppe, 9 c., £111.

CAUSTIC SODA—

Calcutta, 51 t. 16 c., £898.

CHEMICALS (otherwise undescribed)

Calcutta, 10 t. 19 c., £159.; Cocanada, 4 t. 7 c., £76.

COAL PRODUCTS—

Benzole
Dieppe, 5,076 galls., £506.;
Nantes, 258 galls., £26.

Creosote Oil

Horsens, 182,265 galls., £5,486.

Naphthalene

Dieppe, 45,461 galls., £4,320.;
Melbourne, 10 t., £170.; Nantes,
1,296 galls., £123.

Pitch

Antwerp, 1,674 t. 12 c., £5,172.

Toluol

Dieppe, 20, 041 galls., £1,878.

MAGNESIA—

Dieppe, 10 t., £391.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers) ...	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

EDITORIAL NOTICES.

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than Wednesday morning.

CURRENT TOPICS.

FUEL ECONOMY.

THE Fuel Economy Committee of the British Association, owing to the present critical position of the coal industry, have refrained from presenting their final report. That presented at the Bournemouth meeting of the Association on Friday of last week was in the nature of an interim communication. The members of the committee, in the course of their statement, and several of the speakers who took part in the subsequent discussion, criticised the Fuel Research Board of the Department of Scientific and Industrial Research mainly on account of the policy of the Board in holding itself aloof from other bodies and individual workers actively engaged on problems of fuel economy. The Fuel Research Board was established early in 1917, but notwithstanding the offers of the British Association Committee to collaborate with the new body, the proffered assistance was disregarded. The work of the Fuel Economy Committee was suspended until October last, when it resumed its labours "in response to a widespread and growing feeling that there was need of an organised body of independent scientific opinion that could be brought to bear in the public interest upon any proposals for research with regard to fuel." Mr. Robert Mond, who is the nominee of the Association of British Chemical Manufacturers on the Fuel Economy Committee, Sir Robert Hadfield, and Professor Armstrong were among the critics of the Fuel Research Board, the last-named urging that the Board, instead of reserving the work to themselves for investigation, should bring the competent research workers of the country together to discuss and to deal with the problems involved. With that view we have the greatest sympathy. The question of fuel economy is too important a factor in the national welfare to risk the loss that may result through shutting the door on the scientific knowledge that is available outside the personnel of the Fuel Research Board and their staff. What is most needed, as the British Association Committee justly emphasise, is a broadly planned policy which will aim at stimulating and assisting experimental work on the chemistry of coal, fuel economy, and cognate subjects everywhere throughout the whole kingdom. On the other hand, it is too early yet to criticise the Fuel Research Board on the ground of absence of results. For various reasons arising out of the war, the erection of the Research Station at East Greenwich has not been completed, and will probably not be completed much before the end of next year, though a portion of the buildings has been in use for some time. That Sir George Beilby, who is the

Director of the Board, has not been idle since its formation two and a half years ago may be relied upon with confidence. The Advisory Council for Scientific and Industrial Research, in their last annual report, stated that, in view of the cessation of war conditions and of the recent developments in the coal-mining industry, the Fuel Research Board felt it desirable that they should reconsider the whole outlook as regards their researches into the more economical use of the fuel resources of the nation, and a statement dealing with this subject, we are promised, will be issued shortly.

GERMAN ACTIVITY IN SOUTH AMERICA.

DURING the course of the war the agents or branches of the big German chemical manufacturing companies in the States of South America were extremely busily occupied in making preparations for the working up of trade connections with customers and prospective clients of all kinds for the purpose of promoting exports from Germany after the ratification of the Peace Treaty. To those who have become familiar with this work of organisation it is really astonishing what the Germans have endeavoured to accomplish. Acting upon instructions received from Germany, the South American representatives have followed out a programme of dividing up each country—principally the Argentine and Brazil—into a number of districts according to the native trades and industries located in them and likely to become customers for dyes and other chemicals. Having thus mapped out the country, the representatives or their travellers have taken the districts in succession and paid visits to all possible customers in each locality. Naturally all this occupies a large amount of time; but it has to be borne in mind that this organising activity has been extended over a period of five years, and it is possible in this way to cover a lot of ground in the period mentioned, so much, indeed, that the work should have been entirely completed. The results of these visits and inquiries, district by district, have been embodied in reports forwarded to Germany, accompanied by lists of names and addresses of prospective customers and statements regarding the financial standing of each. A similar policy has been also pursued in the case of China and Japan, and it can be easily understood that a mass of information has been collected in this manner of great value to the German chemical industry.

ITALIAN CHEMICAL INDUSTRY.

MANY articles have been published in the past four years concerning the Italian chemical industry, but little notice has been taken of the fact that before the war there was a rapidly growing and fairly extensive chemical and drug manufacturing industry in Italy. The value of such products manufactured in Italy in 1910 was estimated to be approximately £5,000,000. In 1913 this industry employed 12,500 workmen, used 56,000 horse-power, and manufactured products to the value of £7,000,000. The principal chemicals produced were boric, hydrochloric, nitric, and sulphuric acids; caustic soda in solution; sulphates of ammonia and copper; calcium hypochlorite; carbonate of lead (white lead); nitrate of potassium; calcium carbide; calcium cyanamide; glycerine; corrosive sublimate; borax; and chemical fertilisers. Exports in 1913 amounted to about £3,000,000, the principal items being boric, oleic, sulphuric, tartaric, and impure tannic acids, oxide of iron, corrosive sublimate, calcium carbide, citric acid, citrate of calcium, borax, raw tartar, glycerine, and perfumery.

Much progress was made during the war, and numerous small plants were established to manufacture chemicals and drugs which could no longer be obtained from abroad. If the present tariff is retained, many of these will find themselves unable to compete with foreign manufacturers in the Italian

market, although for items such as calcium carbide the tariff is very high. There is a plentiful supply of iron pyrites, and 710,000 tons of sulphuric acid were produced in 1913. A plant in Lombardy, established in 1914, has a capacity of nearly 5,000 tons of nitric acid per year obtained through the utilisation of electricity. Of calcium cyanamide some 17,000 tons were manufactured in 1914. With the addition of sulphate of ammonia, already produced in Italy; calcium cyanamide can be used as a nitrogenous manure.

Before the war Italy retained for use within the country about £4,000,000. worth of the chemicals and drugs of domestic manufacture, and imported additional chemicals and drugs to the value of £6,000,000 per annum. Of the products imported, the following were not manufactured within the country, or, if so, only in small quantities: Chlorides of lime, potash, and soda; chromates of the same; nitrates of all kinds; permanganates of potash and soda; sulphates of all kinds (except sulphate of iron), particularly sulphate of copper; bicarbonates; bisulphides of potash and soda; silicates of all kinds; bromine and bromides; iodine and iodides; acetates of all kinds, particularly of lime; impure acetic acid; arsenic, carbolic, oleic, oxalic, sulphurous, and pure tannic acids; ammonia; caustic potash; impure caustic soda; oxides of lead, tin, and zinc; and non-alcoholic perfumery. Cartridges to fit American-made pistols and exploding caps, both classified as chemicals in the Italian tariff, also find a market. Italy obtains chloride of potassium from Eritrea in considerable quantities. This product was formerly supplied by Germany. There is on hand only a small stock of many of the chemicals mentioned, and the prohibition of import by the Italian Government is all that prevents dealers laying in good stocks. Drugs are also very scarce and high-priced, particularly those manufactured from coal-tar products.

In spite of the efforts of Italian manufacturers to supply the demand for fertilisers, imports of raw nitrate of potash, sulphate of potash, chloride of potash, sulphate of ammonia, Thomas slag, and chemical fertilisers increased year by year before the war. These, with sulphate of copper, made up £2,400,000. of the £6,000,000. of imported chemicals and drugs per annum. Sulphate of copper is manufactured in large quantities in Italy—49,000 tons in 1913,—but the constantly increasing demand offers foreign manufacturers an exceptional opportunity.

Great Britain ranked first in supplying goods prior to the war. Its trade in chemicals and drugs, valued at about £1,440,000. per annum, half of it in sulphate of copper, made up one-fourth of all imports. Germany, supplying about £1,200,000., followed, with trade well distributed throughout the list, although holding almost a monopoly in supplying drugs derived from coal-tar products. France came next with £920,000., also well distributed. The United States exported about £420,000. worth per annum, nearly all in rosin and solid paraffin, the rest being made up principally of oleic acid, oxide of zinc, sulphate of copper, and acetate of lime. The only article of importance from Austria was solid paraffin, which amounted to £190,000. yearly, with sulphate of ammonia to the value of £36,000., second. Belgium furnished £110,000. worth of Thomas slag. The lack of statistics makes it impossible to present an analysis of this kind for the period of the war. The imports of chemicals into Italy increased from £52,000,000. in 1917 to £56,000,000. in 1918, and the exports decreased from £9,200,000. to £5,600,000.

Varnishes containing alcohol pay a heavy duty under the present Italian tariff, and as a consequence imports of this class are small. The average per year for 1910-1913 was 18 tons, of which Germany furnished 53 per cent. and France 9 per cent. In 1917, 15 tons were imported, and in 1918, 14 tons. Non-alcoholic varnishes containing mineral oil averaged 1,033 tons per annum in 1910-1913, of which Great Britain furnished 37 per cent., Germany 33 per cent., France 13 per cent., and the United States 11 per cent. In 1917, 554 tons were imported, the United States furnishing 45 per cent. and Great Britain 42 per cent., and in 1918, 362 tons, Great Britain furnishing 40 per cent., the United States 38 per cent., and France 19 per cent.

In 1910-1913 imports of varnishes other than the two just mentioned, but without alcohol or spirits, averaged 2,089 tons per year; Germany supplied 37 per cent., France 29 per cent., and Great Britain 24 per cent. The United States furnished less than 35 tons. The disappearance of Germany and Austria from this trade caused it to be divided between Great Britain and France. Of the 437 tons imported in 1917 Great Britain furnished 56 per cent. and France 39 per cent., and of the 133 tons in 1918, 64 per cent. came from Great Britain and 31 per cent. from France.—*U.S. Com. Rep.*

THE BRITISH ASSOCIATION.

(Continued from page 279.)

CHEMICAL WARFARE.

PROFESSOR P. PHILLIPS BEDSON, President of Section B. (Chemistry), in opening the discussion on Brigadier-General H. Hartley's paper on "Chemical Warfare" (this *Journal*, September 13, page 278), remarked that one of the sad things of the war was the manner in which scientific knowledge had been prostituted, more especially in connection with gas warfare. It was clear that this weapon would now be permanently established, and chemists would have to take a more active part not only in offensive but also in defensive matters.

Professor H. E. Armstrong, F.R.S., said this was the first public opportunity that had been afforded of thanking Brigadier-General Hartley and his class for the wonderful work they had done on behalf of the nation, and it all went to show what we were capable of when we were forced to do it. He ventured to deprecate, however, the conclusion drawn by the author that the Germans displayed lack of foresight in introducing gas warfare. Nobody could have foreseen what the effects of such a new method of attack would be. He did not believe, as the President had stated in his address, that the system of education alone was at the bottom of the difference between us and the Germans, although it had a great deal to do with it, and if we were aiming to put ourselves on a level with the Germans we must adopt their system of higher education in principle. At the same time, it was the "nature of the beast" which made the German so different from us.

Professor Morgan said that one question had scarcely been touched upon, and that was, "What about the future?" Chemical warfare had come to stay, and within the next 50 years, or even 20 or 10 years, our soldiers would have to go out and face a new chemical warfare; and that being so, it was essential for the military staffs of all nations which looked forward to being aggressors or defenders in the future to investigate the new compounds which could be discovered far more noxious than those already employed, bad enough as they were. He was especially interested in arsenical compounds, and it would be easily possible to find new compounds in this connection more irritating than any used hitherto, and he believed that was true of other compounds as well. At the moment we were losing our war psychology, and were going in for peace and retrenchment all round. Chemical warfare research, however, was not a very expensive matter relatively, and, say, £200,000, a year would enable us to hold a watching brief on what was being done elsewhere. Hitherto most of the research had been done voluntarily, but he thought the time had come when chemists should be well paid for this work.

Professor Armstrong thought the paper of such value that the Section ought to arrange for its publication in full.

The President said that the suggestion would be placed before the committee of the Section.

The author, replying to the discussion, agreed with what Professor Morgan had said about the study of gas warfare being continued during peace time. The whole question of military research was an extremely important one, and if the Section could take some steps to see that a portion of the money now being allocated to research was set aside for the particular purpose referred to, it would be a good thing. By spending large sums on the fighting services without providing for research meant wasting the whole of the money so used.

HIGH EXPLOSIVES.

In the afternoon of Tuesday (September 9), Lieutenant-Colonel C. D. Crozier delivered a lecture on the subject of high explosives. The author, who was Director of Inspection of High Explosives during the war, said that although he was not a professional chemist, he felt that he was in a unique position to put before the Association what an immense debt this country owes to its chemists and chemical engineers—and, in fact, to the whole chemical industry.

Before the war practically every nation used picric acid either direct or with admixture with paraffin wax, and perhaps with some other slight additions. At the commencement of the war, however, our only sources of supply were a few small firms in Yorkshire. As demonstrating how the problem was tackled he exhibited a curve showing that

whereas the total home production in the six months of 1914 was 331 tons, in some weeks in 1917 it reached 1,000 tons per week. In 1918 production was slackened off as T.N.T. and ammonium nitrate forged ahead, but in 1917 the total output was 32,053 tons, which fell to 15,160 tons on December 31, 1918. The production of ammonium nitrate in 1918 was 182,551 tons and of T.N.T. 84,979 tons, the latter falling from 94,796 tons in the previous year. The curve also showed that with all three we did not seriously start manufacture until 1916, the previous year and part of 1914 being taken up in getting to a really large production.

Picric Acid.

Picric acid in 1914 was entirely made by the pot process—a very uneconomical method. Theoretically, 100lb. of carbofic should make 242lb. of picric, but 180lb. was about the average result, and 185lb. was a very good one. Altogether the pot process was not one adapted to large outputs. Numerous cases had occurred of drying stoves getting on fire, and then the picric would burn off violently or actually explode or detonate. It was a peculiar thing that since the war cases of stoves exploding instead of burning off had been more numerous than in peace times. This had been a matter of great concern to the Ministry of Munitions and the Home Office, but so far no satisfactory explanation had been forthcoming. Very great improvements, however, had been made in isolating the "dry end" of picric works from the "wet end" where the nitration and washing was carried out. In order to improve the supplies of picric acid the dinitrophenol method was adopted. Dinitrochlorobenzene was a product largely manufactured in peace times by the United Alkali Company for the manufacture of aniline dyes, and the conversion of this into dinitrophenol was worked out and put into operation by this company. The problem then was to further nitrate this dinitrophenol into dinitrophenol or picric acid—that is, to add the third nitro group. This problem, which opened up a totally new field of supply, was entrusted to Major L. B. Holliday, of the newly-formed firm of L. B. Holliday and Co., Ltd., of Huddersfield, and in all 7,988 tons of the very best picric acid was delivered by the company by this process. Meantime, very great improvements had been made over the old pot method of making picric acid, and the new factory of Holliday's was illustrated as typical of the great change that had come over the method of manufacture.

The considerable stocks of synthetic phenol which were accumulating made it desirable to consider an improved method for the direct nitration of picric. In view of the experience gained by Major Holliday in the D.N.P. nitration process, and from experiments carried out in his factory, the Ministry of Munitions decided to erect a new factory at Bradley, built to the design of Major Holliday, for the direct nitration of phenol in large quantities in large enamelled vessels instead of by the old pot method. Major Holliday, in bringing both these processes to a successful issue, had proved himself a pioneer in the manufacture of picric acid.

There was another and quite novel process of making picric which the war had produced, known as Brooke's continuous process. Early in the war Mr. Newton Brooke, who previously had not had anything to do with the chemical industry, started making picric acid on the old pot method, but, dissatisfied with the labour involved in this, started to devise something else. The continuous plant which had been devised consisted of an acid-proof brick tank about 160ft. long, and a tank of this length would produce 20 to 30 tons per week continuously. The phenol sulphonic acid, diluted with water, was first made, and entered the plant at one end; the nitric acid, of 65 per cent. strength, is admitted by a series of aluminium jets. It comes in contact with the phenol sulphonic acid, and the reaction at once commences. A little waste nitration acid is allowed to flow along with the phenol and nitric acid, and it acts as a carrier for the picric acid, both by solution and mechanically, by increasing the flow through the trough. When nitration is complete, the picric acid moves forward through cooling sections of the trough, and is finally delivered at vacuum filters, where it is separated from the waste nitration acid. The picric is then washed in the ordinary way. An essential feature of the process is the low temperature of nitration, which, on the average, does not exceed 102° C., thus saving oxidation of the

phenol as in the pot method, where temperatures of 115° and even 120° C. are frequently experienced. With a prolonged run, the yield of picric on the original weight of phenol was found to be 194 per cent., against 180 per cent. with the pots. Altogether it was a very convenient process to work, and Mr. Brooke and his chemists were to be congratulated on their enterprise. They came new to the trade, and had certainly achieved quite a new departure.

T.N.T.

Turning to T.N.T., here, again, said the lecturer, the methods of manufacture had been considerably improved. The biggest factory for the production of this was at Queen's Ferry, Chester, which delivered some 55,000 tons. This factory, and also that at Gretna, which was devoted to the production of propellants, were outstanding monuments to the genius of Mr. K. B. Quinan, and although he had read some criticisms of these factories, he had yet to read how the war could have been won without them. The other great factory and rival of Queen's Ferry in the production of T.N.T. was H.M. Factory, Oldbury, managed by Messrs. Chance and Hunt. In addition to a great deal of useful experimental work, an entirely novel method of manufacture of T.N.T. by a continuous process was evolved, and eventually the whole of the T.N.T. was turned out by this process. He was not, however, at liberty to give details, but it was a method he should like to employ if he were a T.N.T. manufacturer.

Ammonium Nitrate.

Owing to the great demand for high explosives, it was found necessary to devise means for making the T.N.T. go further, and this was effected through the agency of ammonium nitrate, and the mixture of these two was known as amatol. In all, 378,395 tons of ammonium nitrate were provided, and the simple method of mixing nitric acid and ammonia to make ammonium nitrate was quite impossible to supply the huge war consumption, as less nitric acid than ever was available. Here the well-known and progressive firm of Brunner, Mond and Co. came to the rescue, and they undertook the manufacture of ammonium nitrate, in addition to many other products. Altogether nine large separate and distinct installations in England were employed by them either directly or under their control. At first it was made from Norwegian nitrate of lime, but the supplies of this were inadequate, and Brunner, Mond and Co. adapted plant at their Lostock works to make ammonium nitrate directly from sodium nitrate by reaction with ammonium bicarbonate—a process of great complexity and difficulty, the chemical equilibria involved being most delicate. Still the cry came for more ammonium nitrate, and it was decided to make calcium nitrate at home. The raw material was at hand in the form of calcium chloride, which was a waste product of the ammonia-soda process. The very large Victoria Works at Wincham, Cheshire, were designed and built with the greatest possible speed to supply the ever-growing demands for this calcium nitrate, and Lostock, where the conversion took place, had to be enlarged to deal with these large supplies.

All this time, in spite of what had already been done, a long and difficult laboratory investigation was being carried out by Brunner, Mond's research staff, and they capped their previous efforts by working out an entirely new process for the direct preparation of ammonium nitrate from ammonium sulphate and sodium nitrate. This new sulphate-nitrate process was put into operation first at the firm's Sandbach works. It proved very successful, and a large plant was erected at Swindon from the experience gained at Sandbach. The United States Government Commission, after a careful study of the various processes, decided to adopt the new sulphate-nitrate process, and the huge works at Perrivale, Maryland, with a producing capacity of some 3,000 tons per week, was working the process with great satisfaction. For these works, Brunner, Mond and Co. supplied the plans and details.

Ammonium Perchlorate.

Finally, the paper dealt with ammonium perchlorate explosives, which, being more sensitive than ammonium nitrate, were not used in gunshell. They were, however, used extensively in submarine mines, and the principal minefields across the North Sea were filled with ammonium perchlorate explosives, of which the perchlorate was manufactured by the United Alkali Company at their works at Flint. The great advantage of ammonium perchlorate was that it could be made in this country from our own raw materials. The

details of the process, however, were secret. The erection of the plant was begun at the end of 1915, and manufacture on a commercial scale was commenced on October 1, 1916. The output was 60 tons per week.

In concluding his paper, the author gave an account of the formation of the Explosives Department, and paid a tribute to the work of the universities contiguous to manufacturers—viz., Birmingham, Leeds, Liverpool, Manchester, and, later, Edinburgh,—and their chief officials, for assistance in regard to testing the vast quantities of explosives that went through their hands. Due to this assistance, the cost of inspection of £100 sterling worth of material was only a few pence. He also expressed the thanks of the Department to the manufacturers for their assistance, and, incidentally, expressed the hope that the Press, which was always accusing Government Departments of waste, would sometimes look on the other side, and give credit for good work done.

Professor H. B. Dixon proposed a vote of thanks to the lecturer.

Sir Robert Robertson, in seconding, said that after the achievements of the highest technical order which had been attained at Queen's Ferry, the plant and buildings there should be taken advantage of. He had suggested that it should be turned into a university, with Mr. K. B. Quinan as principal. That was off, but some use should be made of the Queen's Ferry works because of the multitude of technical matters which were dealt with there, and the manner in which technical difficulties had been overcome.

In a paper on Wednesday (September 10), on

SOME GEO-CHEMICAL PROBLEMS DEALT WITH DURING THE WAR,

Professor P. G. Boswell said that the borderland between chemistry and geology was a wide country, but imperfectly explored. It seemed that the stress of war was needed before its little-known tracks could be re-trodden and extended. The co-operation of pioneers pushing forward from both sides of the border had led to the clearing away of much of the undergrowth of doubt, and to the consequent discovery of alternative routes and the new paths to knowledge. Many of these essays into the unknown had been admittedly exploratory and opportunistic; others had resulted in the discovery of ways and means the value of which ensured their permanent retention. In either case the results had justified the early work, and served to emphasise the benefit accruing to the community from the co-operation of the chemist in the laboratory and the geologist in the field.

The question as to the exact scope of the subject of geochemistry was perhaps a debatable one. A well-known American authority had expressed his view of the functions of the geochemist thus: "To determine what changes (in the rocks constituting the earth's crust) are possible, how and when they occur, to observe the phenomena which attend them, and to note their final results. . . ." In the course of pleas made recently for the establishment of a Geo-chemical Institute in this country, the connotation had been extended to include not only the chemical investigation which was required before problems like those outlined above could be solved, but also chemical research dealing with and controlling the industrial uses to which rocks and minerals might be put. As would be expected, the industrial application of our knowledge of geological raw materials had been the outcome of pure scientific research. On the other hand, in the course of the solution of practical problems much information of real value to the man of "pure" science had accumulated, and in due time the results would become available. One outcome of these extended geochemical investigations had been the replacement of certain rock and mineral substances hitherto imported from abroad by British materials—either precisely similar in character, or as substitutes "just as good," at times distinctly better, and at other times of the character of makeshifts. Not only was shipping thus relieved, or, in the case of certain substances of enemy origin, deprivation overcome, but at the time of the great strain upon internal means of communication and transport it was found possible to indicate suitable sources of raw materials close to works requiring them. In this way carriage was reduced and coastal trade and railway transport diverted into less congested areas.

Shortly after the outbreak of hostilities many British industries connected with the output of munitions or the maintenance and increase of food supplies, found themselves wholly or in part deprived of certain essential raw or "semi-manu-

factured" materials of mineral origin. As examples might be mentioned the key industries of glass-making, and steel manufacture (in particular, steel-founding) which suffered from the shortage of potash, glass-sands, moulding-sands, etc., besides other chemical materials made from mineral products. In connection with food supply, the lack of nitrates, potash salts, and phosphates became acute. The chemists solved the nitrate difficulty by the fixation of atmospheric nitrogen. The investigation by the geologists and mining engineers of home supplies of potash-bearing minerals, such as feldspar, and the recovery by the chemist, in co-operation with the geologist, of potash from blast-furnace flues in Britain and cement-kiln flues in America, temporarily overcame the difficulties produced by the absence of German salts. The coprolite-bearing deposits of the Cambridge green-sand were after some delay opened up for the purpose of obtaining the contained phosphate of lime, and at the date of the armistice were yielding helpful supplies.

The impetus given to the working of home supplies of metallic minerals such as the ores of iron, copper, lead, zinc, tin, and tungsten, and of veinstones like barytes, fluor spar, and quartz, were familiar to all. The treatment of the ores and the manufacture of "intermediate" products like ferro-tungsten demanded the co-operation of the metallurgical chemist.

Geochemical research had shown that the quality of silica-bricks made by burning at a temperature of over 1300° C. a ground-up mixture of gannister and other siliceous rocks, with 1 per cent. of milk of lime as a bond, might be appreciably improved by burning the bricks for a longer period at a higher temperature than was previously the practice. Greater inversion of the quartz to other low-density forms of silica occurring occasionally in rocks, and known as tridymite and cristobalite, was thus ensured, with the consequence that less expansion of the brick subsequently occurred when it was set in the furnace.

For the successful laying down of specifications of refractory materials for particular purposes, a task which was undertaken before the war by the Institution of Gas Engineers, and during the war by the Society of Glass Technology and the Iron and Steel Institute, a large amount of geochemical research was, and is still, required. Cognate problems were met with in the production of laboratory porcelain, hard paste, etc. In the Potteries, British feldspar, sand, and flint were substituted for the unobtainable foreign supplies. In consequence of the cutting off of supplies of Austrian and Greek magnesite, the home resources of dolomite had been largely drawn upon, with noteworthy success.

A danger existed that in consequence of the cheapness of foreign supplies of raw materials, and of the lowness of the through freight-rates from adjacent Continental countries, it might be impossible to continue to work British supplies of these materials. It was the energetic exploitation of these mineral resources, so essential for key industries, which saved the situation time after time during the war. A renewal of dependence upon foreign resources is not only grossly unfair to those who have laid down plant and sunk their capital in British mineral enterprises during the last four years, but was a source of grave national danger, inasmuch as it placed the country in precisely the same position as that which arose during the early months of the war. If it was not possible to impose restrictions on the importation of certain foreign raw materials, recourse must be had to the revision of railway freights and the rapid development of internal water transport.

GLASS MANUFACTURE AT THE END OF THE WAR.

Dr. Morris W. Travers, F.R.S., in a paper on this subject, on Wednesday (September 10), said that circumstances arising out of the war had done much to dissipate the idea that success in industry depended upon the possession of trade secrets. The Society of Glass Technology, and the new trade associations, had already done much to bring manufacturers together, and to promote the spirit of co-operation. Thus the way had been paved for the formation of a Glass Research Association under the Government scheme for industrial and scientific research. Such research as had been carried out during the war had aimed rather at the solution of problems arising out of the need for producing goods previously imported from enemy countries, and it was difficult to lay one's hand on a really original discovery in connection with glass. However, the lines which future investigations must follow were fairly well defined.

It was generally recognised that at a comparatively early stage in the war, British manufacturers succeeded in producing glasses for many essential purposes which compared very favourably with the foreign goods, but it would be unfortunate if they failed to realise that there was yet scope for improvement. No resistance glass for chemical glassware had yet been discovered which was sufficiently highly resistant to all ordinary reagents to be considered to be an approach to perfection. It must be admitted that the lamp workers (workers at the table blowpipe) had reason to be highly dissatisfied with the general quality of the tube with which they had to work. The poor quality of much of the tube manufactured in this country was due to the fact that the furnaces were not capable of working at high enough temperatures. Investigations with a view to the improvement of glasses for thermometers, for all kinds of scientific goods, and for ordinary domestic and commercial glassware, should be pressed forward.

Almost nothing was known of the chemistry and physics of the founding and plaining of glass: exactly why it was, for instance, that a checked pot of metal would not plain, or how and why the various kinds of cords were formed. We had very little quantitative knowledge of the properties of plastic and liquid glass, and very few attempts had been made to work out methods of investigation. The viscosity of glasses, about which nothing was known, was a matter upon which information would be of use to manufacturers who employed mechanical methods of glass-blowing. There was, said the author, considerable scope for investigations on the materials used in the glass trade, particularly with a view to substituting cheaper materials for those in use before the war. The best quality of resistance lighting ware manufactured in Austria before the war contained a large proportion of boric acid, which would make the goods almost prohibitively expensive at the present price of borax. A good deal had been done during the war in the way of substituting soda for potash in glasses, but the results, at least so far as glass for electric-lamp bulbs and lamp-working tube were concerned, had not proved satisfactory. The influence of ingredients of glasses, such as magnesia and alumina, which had generally been introduced into glasses accidentally, as impurities in the raw materials, was a subject for research. In 1915 it was still possible to obtain Swedish feldspar containing 13 per cent. of potash and very little iron, delivered flour-ground in London at less than £3. per ton. During the present year the cost of Cornish feldspar, containing 10 per cent. of potash and a considerable amount of iron, delivered in lumps in London, was over £7. per ton. The difference in the quality of the material was even more important than the increase in price.

Except in some of the larger works, very crude methods were employed in the handling and treatment of materials, and in this the glass trade might be considered to be very backward. The best methods of grinding and mixing batch and cullet, and the use of magnetic separators, conveyors, etc., in the industry really required investigation. The treatment of different kinds of material required special study. On the proper treatment of the materials and the mixing of the batch depended the quality of the glass, and the saving of loss due to stones and cords. Glassmakers cordially disliked machinery, but they would have to put up with it if the trade was to hold its own against foreign competition. Success or failure in every branch of the industry depended in a great measure on the efficiency and economy with which the metal, or molten glass, could be produced. Furnace problems therefore ranked high in importance, and first amongst furnace problems came those which related to the manufacture and treatment of refractory materials. Refractories in the glass industry had to withstand not only the high temperatures, but also the fluxing action of glass, and must therefore be studied from the particular standpoint of the industry.

The problem might be illustrated by reference to pot furnaces. In the old days of direct firing, the pots were filled on Friday afternoon, so as to be ready for working on the Monday, and some of the pots might have been filled and plained once again during the week. Such furnaces were often built of green clay blocks, which were fired in position, and lasted for years. With the introduction of semi-gas-firing, and gas-firing without recuperation, higher temperatures were attained, and production was intensified, as it was possible to fill and plain each pot in the furnace two or three times in the week, provided that the pots were emptied quickly enough. Such furnaces burned out in about two years, and trouble was

experienced with the pots. No doubt failures were in a considerable measure due to a lack of understanding of the proper treatment of refractories on the part of the glass manufacturers, but it also became clear that improvement in the quality of British refractory materials was highly desirable.

At the moment special interest attached to certain branches of the industry which were scheduled for protection in accordance with the new trade policy—viz., optical glass, including lenses, prisms, and like optical devices, scientific glassware, and illuminating glassware. The country was now practically self-supporting with regard to scientific hollow-ware, and it might be hoped that the labours of the Standardisation Committee of the Society of Chemical Industry, which had aimed at the standardisation of chemical apparatus, would be of value to the industry. The output of lamp-blown apparatus and of graduated apparatus had increased enormously, but it might be anticipated that that branch of the industry would meet with keen competition, particularly for the supply of such articles as test tubes, which required cheap labour such as was available in Central Europe and Japan. The scientific public, critical of home-made goods, had suddenly awakened to the fact that much of the imported graduated ware was very inaccurate, and were insisting on a higher quality of goods, which the British manufacturers were succeeding in supplying.

Sir Robert Hadfield, F.R.S., said he was interested in this paper because he was particularly anxious to know where it was possible to obtain the best glass for lenses in connection with micro study. He was informed that at the present time we were still dependent upon German and Austrian lenses if the very best quality was to be used.

Mr. W. S. Chalmers said the most important difficulty in the manufacture of British lenses was the computation. Another difficulty was the supply of good transparent fluorspar, which was an essential constituent of most of the best and high class lenses. He believed that British manufacturers were now at work in directions which were not possible before the war, and even during the war; and provided there was sufficient demand for their products to justify the expenditure of the necessary large sums of money on plant, the British manufacturer could produce as good an objective as the foreigner, as had been the case during the war, when very large sums were so spent.

Professor C. H. Desch said his experience had been exactly that of Sir Robert Hadfield, but he would like to point out that in certain classes of optical work we had led the world. The range-finder was an instrument which was perfected in this country and had been manufactured here during the war. The optical work involved in the latest pattern of range-finder, including the 30ft. naval instrument, surpassed anything done in the works of Zeiss or Goerz. The degree of accuracy in these wonderful prisms had never been touched by the German firms, and the British firm which now manufactured them was responsible for its own optical glass, which was the finest he had ever seen. If we could have the same standard of skill reached in the manufacture of lenses he did not think it would be long before British lenses would be made equal to the foreign ones. The computation, as Mr. Chalmers had said, was perhaps the most difficult part of the work, but a tremendous amount had been done in that direction, and certain publications—mostly translations from German works—recently made would greatly facilitate work on all kinds of objectives in the future.

METALLURGY DURING THE WAR.

In a paper on Wednesday (September 10), Dr. C. H. Desch briefly outlined some of the developments in the countries of the belligerents in regard to metallurgical matters. Having discussed the position with regard to iron and steel in Germany, he said that the shortage of copper was a much more serious problem for our enemies. For supplies of this metal Germany was principally dependent upon the United States, and our blockade was undoubtedly successful in preventing the metal from entering. The German production of copper from the Mansfield mines was previously small, and although it had been increased to the utmost it was only able to replace a small part of the large requirements of the country for munition and electrical purposes. There were large stocks in hand at the outbreak of war, and Serbia and

Asia Minor, both of which possessed important deposits of copper ores, furnished a certain quantity, but the shortage was undoubtedly severely felt. Much was done, however, to make use of substitutes. Aluminium, iron, and zinc were employed for the winding of dynamos and motors, with successful results, and it was claimed that aluminium was cheaper than copper for winding transformers, and that some manufacturers intended to continue to use it commercially. So far as copper was concerned, however, the Allies were in a far stronger position than the Central Empires in regard to future supplies.

The position of zinc was a remarkable one. The United States used to be the largest producers of the metal, followed by Germany and Belgium. Belgium, however, made use of imported ores, her own deposits being no longer of great importance. Speaking with regard to the Australian zinc ores, Dr. Desch said that these were complex and difficult to smelt, and the Germans, having obtained control of them, devoted much attention to the problem of their treatment. It was not correct to attribute the loss of this important industry to this country to the apathy of Governments or to unfavourable fiscal conditions, and a share of the blame must rest on the mine-owners and smelters who had failed to devote to their industry the necessary scientific investigation which would have solved the admittedly difficult problems presented by the concentrates. Smelting works had now been set up both in Australia and at home, and it was to be hoped that the British zinc industry would once more occupy a foremost place. For this to happen, however, it was essential that close scientific control should be exercised and that steps be taken to improve the metallurgical methods, which had lagged behind the practice of other countries. In this connection it was disappointing to observe, in the reports of the alkali inspectors, that in the new works for the smelting of zinc which had been erected here, the sulphur dioxide produced by the roasting process was allowed to escape into the air. Such a practice was harmful in every way, the destructive action of the gas being very serious, whilst the waste involved resulted in most uneconomical working. A large proportion of the sulphuric acid manufactured in Germany obtained its sulphur from the roasting of zinc ores, and one of the lessons most forcibly brought home to us by a comparison between German and British methods in the chemical industry was the absolute necessity of the utilisation of all by-products if success was to be obtained.

Mr. ROBERT MOND, in the course of the discussion, said the world's production of non-ferrous metals before the war was 3,000,000 tons per annum. Great Britain's consumption was 450,000 tons and her actual production was 150,000 tons per annum, whilst her production of metal from her native ores was only 15,000 tons per annum. This demonstrated that Germany's idea that it was only possible to build up a trade or industry by politically possessing the sources of raw materials was one of the most fundamentally false ideas that ever crossed the human mind. The best policy was to obtain our raw materials wherever they could be obtained and then to develop the best methods for dealing with them. The history of British industry during the last 40 or 50 years was that although we had access to most raw materials, and had been the possessors of them in most cases, scientific manufacture in our industries had always been behind, although cases could always be brought forward in which we were ahead of other nations. That, however, only applied to one or two firms in any industry. The cause of that was the prevalence of the idea that what was good enough for our forefathers was good enough for us. During the war, with unlimited means at our disposal, we had brought many an inefficient manufacturer to the level of the efficient, and if that were possible under war conditions it should be equally possible in ordinary commercial conditions.

Dr. Walter Rosenhain said that our war experience with cupro-nickel was an instance which showed very clearly how deficient we were in a good deal of our fundamental knowledge. In this and in all these light alloys, what was wanted was better backing for research by manufacturers. Thanks largely to research by Mr. Hartley, of Sheffield, all the difficulties of rolling cupro-nickel were overcome, and it was seen that their was no real difficulty in rolling this material once a sound ingot was obtained. That, of course, was true of all metals. Another important development during recent years was the use of light aluminium alloys for aircraft purposes, and its undoubted value for aircraft engines had been proved.

Mr. Cosmo Johns said that as the result of visits which he had paid to the left bank of the Rhine since the armistice he was convinced that the Germans had made practically no metallurgical progress during the war. Her manufacturers had suffered from too many difficulties, and it was astonishing that they had been able to struggle on as long as they did. There was a great scarcity of copper and aluminium, whilst tin was practically unobtainable owing to the blockade. The chief substitute for tin was zinc, a most unsuitable metal, but it had to be used for the most extraordinary purposes. The lack of essential metals and the breakdown of transport through lack of good bearing metal and lubricating oils were the chief things which brought Germany to the end of her resources.

BACTERIOLOGY: ITS PRACTICAL APPLICATION AND ITS IMPORTANCE OUTSIDE MEDICINE

was the subject of a paper read by Dr. A. C. Thaysen on Thursday (September 11). Since the days of Pasteur, Robert Koch, and Lister, said the author, bacteriology has been recognised as a special branch of science devoted to the study of the microscopic unicellular organisms commonly known as bacteria. However, in spite of official recognition, bacteriology is by no means yet an independent science. It still remains allocated to quite a number of arts and sciences with which it was associated in its earlier history, and it is still taught and studied in relation to them. There can be no doubt that sooner or later an attempt will have to be made to co-ordinate the various branches of bacteriology already existing, and to centralise and standardise the teaching of this science. In the hope of being able to increase in some small degree the interest taken in these other branches of bacteriology, a brief account was given of some of the various spheres of activity of the non-pathogenic bacteria.

By far the best known application of micro-organisms to industry is the conversion of sugar into ethyl-alcohol, mostly in the form of wines and beer. The brewing of beer and the making of wines are industries as old as history itself, but it is only within the last 30 years that they and the responsible micro-organisms have been brought under scientific control. Much work, both theoretical and practical, is still needed in this field, which to-day has attained added interest through the application of yeast for the manufacture of glycerine and fuel for internal-combustion engines. Closely related, both industrially and historically, to the production of beer and wine is vinegar manufacture. Here the conversion is brought about by a true *schizomycet*, which oxidises ethyl alcohol to the corresponding aldehyde, and thence to acetic acid, or, in the presence of oxygen, to carbon dioxide. Pasteur's, Hansen's, Buchner's, and Brown's subsequent researches have cleared the way to the right interpretation of this reaction, but, unfortunately, the actual manufacture of vinegar is still far from satisfactory. Far too little attention is being paid to the value of the introduction of pure cultures and the consequent improvement in the control of the degree of oxidation. As a side issue, it would be of interest to investigate further the property of some of the acetic bacteria to oxidise higher alcohols—for instance, butyl alcohol—to the corresponding acids. It might perhaps in this way be possible to manufacture butyric acid at a lower price than by chemical oxidation of butyl alcohol or by direct fermentation of carbohydrates.

The manufacture of butyl alcohol and acetone attracted considerable attention both in this country and abroad during the war. The enormous demand for one of the products obtained necessitated the construction of gigantic plants. In a factory erected by the Admiralty for the production of acetone, a weekly output of this chemical of 30 tons was planned. The fermentation tanks had a capacity of 150,000 gals. each, making it possible to convert 35 tons of raw material during one fermentation. The conversion of the carbohydrates used took 34-36 hours to complete, so that with two fermentations proceeding simultaneously two tons of raw material could be dealt with hourly. For the successful conversion of the carbo-hydrate it was essential that foreign micro-organisms should not gain access to the vats, either before or during the fermentation—a somewhat difficult problem to solve on such an immense scale. Eventually success was met with, and from that time onward the conversion of the carbo-hydrates into acetone could be most successfully completed, and considerably more than 99 per cent. of all the fermentation were free from serious infections with foreign bacteria. The investigation of the theory of this fermentation led to a rather interesting discovery. On

examining the fermenting liquid, it was found that appreciable quantities of acetic acid were formed as an intermediate product, and again mostly disappeared toward the end of the fermentation. On increasing the acid content of the fermenting liquid by the addition of acetic acid in concentrated or dilute form, it was found that 80 per cent. of the acid added had been converted into acetone at the end of the fermentation. A far more efficient method than the old dry distillation of calcium acetate had thus been formed for the conversion of acetic acid into acetone. The addition of acetic acid on a large scale up to 100,000 gals. of fermenting liquid has been tried, and found as successful as the laboratory. Other fermentations which might be technically applied were the conversion of carbohydrates into lactic acid and the production of citric acid.

Time after time, in reviewing the development of bacteriology, there is evidence of lack of co-ordination which for far too long had been allowed to exist, and which, unless treated seriously, is liable to remain one of the greatest obstacles to progress.

FUEL ECONOMY.

A discussion took place on the report of the Fuel Economy Committee presented to Section B (Chemistry) on Friday (September 12). In the absence of the chairman of the Committee, Professor W. A. Bone, F.R.S., the report was presented by Mr. Robert Mond, Secretary of the Committee:

In its first report the Committee drew attention to the vital importance of relatively cheap coal to the nation's industrial prosperity, and stated that, for some years before the war, the average price of coal at the pithead had been decidedly on the up-grade, a tendency which might be expected to continue at an accelerated rate. As the result of circumstances created by, or arising out of, the war, the average pithead price of coal has already almost trebled since the year 1913, and is likely to rise still higher, a matter of most serious concern to the whole nation.

How basic is the necessity of relatively cheap coal to the recovery of our pre-war prosperity will at once be apparent when it is realised how absolutely dependent are all our principal manufacturing industries upon imported raw materials. Our own natural resources do not enable us to provide ourselves, in quantity sufficient for the needs of a modern industrial community, with a great variety of raw materials; nor can we grow sufficient food for our present population. But our ships can bring abundance of raw materials from all parts of the world to our coal. Without the impelling power of relatively cheap coal we should neither be able to attract the raw materials, nor yet to build or maintain the ships in which to convey them. Relatively cheap coal is, in fact, a fundamental necessity to the maintenance, not only of our great iron, steel, engineering, ship-building, and textile industries, but of our shipping trade and sea power.

Outputs of Coal and Average Pithead Prices in Great Britain.

Year.	Total Output Million Tons.	Annual Output per person employed Tons.	Average Pithead Price per Ton.
			s. d.
1913	287.4	260	10 1
1914	265.6	238	10 0
1915	253.2	270	12 6
1916	256.3	260	15 7
1917	248.0	247	16 9
1918	227.7	232	(24 0) ¹

¹ Estimated.

Prices per ton paid by Consumers in Great Britain.

Year.	In London for Best House Coal delivered.	For Gas Coal by the South Metropolitan Gas Co.		For Durham Coking Coal at a Cleveland Ironworks. ²
		f.o.b. at N.E. Coast.	Cost into Works.	
	s. d.	s. d.	s. d.	s. d.
1914	29 0	11 2	14 6	13 0
1915	34 3	15 5	22 11	16 2
1916	37 0	16 5	26 4	22 3
1917	38 0	16 8	32 5	22 10
1918	44 0	20 11	34 4	24 5

² The corresponding pithead prices would be about 3s. 6½d. less than these. The average price (at the works) during the first six months of 1919 has been 26s. 6d. per ton.

The great need of the moment is that the true facts of the situation shall be brought home to all sections of the community. The Committee, therefore, desires to draw

attention to the accompanying comparative data concerning the movement of coal prices in Great Britain and the United States during the war-period. In converting the American prices into their English equivalents a dollar has been taken as 50 pence.

The upward tendency of prices has continued since the close of 1918, and, according to a recent declaration made on behalf of the Government in the House of Commons, consumers will have to face an all-round increase on the foregoing prices of 6s. per ton during the coming winter.

The Committee views with concern the recent rapid decline of the annual outputs per worker employed in British mines. During the thirty years preceding the war the returns had shown a steady decline, as follows:—

Decade.	Average Annual Output per Worker Tons.
1883-92	320
1893-02	295
1903-12	280

That this downward tendency was peculiar to British mines is shown by the following comparative figures:—

Comparative Annual Outputs per Worker employed in the Mines in

Triennial Period.	Great Britain.	Germany.	United States.
	Tons.	Tons.	Tons.
1905-7	289	248	589
1908-10	265	239	591
1911-13	254	263	651

During the war the British outputs have continued to fall at an alarming rate, until in 1918 they reached the low level of 232 tons per worker employed. In marked contrast to this, the American figures have continued to rise at an accelerated rate until in 1916 they reached 732, and in 1917 the phenomenal record of 768, tons per worker employed. It would thus appear that in the year 1917 the American output per worker employed was more than three times that realised in British mines.

The following figures may be given, as showing how the wholesale prices of typical classes of American fuels have moved during the war:—

Average Wholesale Prices of Coal and Coke per Long Ton in the United States for each Year since 1913.

	Stove Anthracite at New York.	Semi- bituminous Pocahontas f.o.b. Norfolk, Va.	Bituminous Pittsburg, Run of Mine, f.o.b. Cincinnati.	Connellsville Coke.
	s. d.	s. d.	s. d.	s. d.
1914	21 1	12 6	10 3	8 5
1915	21 0	11 10	10 3	8 4
1916	22 9	15 6	12 6	15 2
1917	23 5	22 8	21 5	38 6
1918	27 1	18 8	18 1	28 0

From the examination of the monthly returns it appears that, with the exception of those of anthracite, American wholesale coal and coke prices rose sharply during the latter half of 1916, and reached a maximum about the middle of 1917. Thus Pocahontas reached a maximum of 29s. 2d. (f.o.b. Norfolk, Va.) in May-June, 1917, and bituminous one of 28s. per ton (f.o.b. Cincinnati) at the same period. Connells-ville coke, which is that used in the Pittsburgh blast furnaces, touched a maximum of 57s. 2d. per ton in 1917. After that period prices fell "under control." Thus Pocahontas fell to a minimum of 16s. 3d. in August-October, 1917, since which time they have steadily risen until in April, 1919, they were at 20s. 5d. per ton. Bituminous fell to 14s. in September-October, 1917, but have since risen to 18s. 8d. per ton (f.o.b. Cincinnati) in April, 1919. Connells-ville coke kept at 28s. for a period of fifteen months, from October, 1917, to December, 1918 (both inclusive), since which it has steadily declined, month by month, until in April, 1919, it stood at 18s. 2d. per ton. In the same month the price of Durham coke at the ovens was 33s. per ton *plus* a subsidy (paid by the Government) of 5s. 7d. per ton. It thus appears that already American fuel prices have fallen to a level considerably below those ruling in this country, a circumstance which gives American manufacturers a great initial advantage over our own.

Research on the Chemistry of Coal.

Since the previous report, Professor Bone has continued to direct the research work upon the Chemistry of Coal at

the Imperial College of Science and Technology, London, which he originally undertook in 1916 at the instance of the Committee. In conjunction with Mr. R. J. Sarjant he has recently published, in the "Proceedings of the Royal Society," the results of a series of experiments upon the so-called solvent action of pyridine upon coal, to which Bedson first drew attention in the year 1899. Since that time it has been investigated by a number of other chemists as a possible means of discriminating between the chief types of constituents of the coal substance. Wheeler and his co-workers have employed it extensively in their researches, claiming that if the portion of the coal removed by pyridine be subsequently extracted with chloroform, a complete separation of the resinic from the cellulosic constituents may be effected. On the other hand, the independent work of Harger, Wahl, Vignon, and others raised the question whether the action of pyridine, and other similar basic solvents, is really one of ordinary solution, and much of the evidence obtained by them suggested that it is chiefly a depolymerising one. Professor Bone's recent experiments support this latter view, and point to the conclusion that the action in question affects the coal substance as a whole, and is by no means confined to any one constituent of it. The action is retarded, in a degree which may vary considerably according to the character of the coal, by the presence either of water in the solvent or of oxygen in the atmosphere in which the extraction is carried out. In order to obtain comparable results with a series of different coals it is, therefore, necessary to operate with a carefully dried solvent, and in an atmosphere from which oxygen is excluded. Suitable means and apparatus have been devised for carrying out extractions under such precautions. It has also been shown that the action of pyridine at its boiling point (under atmospheric pressure) upon a particular coal approaches in time a practical limit which, however, may be considerably exceeded if the extraction is carried out at higher temperatures (*e.g.*, in sealed tubes under pressure). Professor Bone and his co-workers have also devised a method for extracting in a pure condition the resinic constituents of coal, particulars of which will shortly be published.

In connection with the question of the organisation of systematic investigations upon the chemical characters of the principal British coal seams, this Committee desires to reiterate the opinion expressed in its first report—namely, that "the resources, both of existing laboratories which have been established in this country for the special investigation of fuel problems, and of other laboratories where the technique of the subject has been developed, might be utilised more than they are in this connection, and that the time is ripe for the organisation of a scheme of systematic co-operative research aided by national funds in which all such laboratories may participate."

The Committee regrets to say, however, that, notwithstanding the establishment of the Fuel Research Board, with large funds at its disposal, no attempt has apparently yet been made to organise any such comprehensive scheme as was recommended in 1916; and it wishes again to impress upon both the public and the Department of Scientific and Industrial Research the danger of sterilising fuel research by a policy of over-centralisation. On the contrary, it is of the opinion that what is most needed is a broadly-planned policy which will aim at stimulating and assisting experimental work on the chemistry of coal, fuel economy, and cognate subjects everywhere throughout the whole kingdom.

Mr. Mond, in presenting the report, said that copies of the Committee's first report were laid before the Fuel Research Board in the hope that some of the recommendations made in that report would be carried out. The Board, however, had done nothing to carry out a systematic research upon all coals in this country in the same way that had been done in America. If all the coals in this country were analysed and classified it would be possible to put them to their best uses. One large chemical firm with which he was connected, tested and classified all the coals they used, and the results were given to the Government, and had been found extremely useful, but that was not the way to deal with this problem. Being anxious that there should be a survey of the coalfields of this country, the Committee had approached the Fuel Research Board with a view to a certain sum being set aside for this purpose, as it was beyond the means of the Committee to do this work. The British Association Committee, said Mr. Mond, had not, in the present report, devoted much attention to artificial fuel; that would be dealt with in the next report.

Sir Robert Hadfield, F.R.S., said there was no doubt that this country had been very wasteful in the use of coal in the past, but it did not apply to this country only. In America the waste was prodigious, and steps would have to be taken there also to deal with the problem. Indeed, a report would shortly be issued by the Mineral Resources Bureau of Washington. On this important matter they should pool their knowledge and researches; moreover, it was time that the Fuel Research Board threw a little light on the work it was doing. A good deal of money was being spent by it, and he was sure that some information would be welcomed and would be of advantage to the country at large.

Mr. C. E. Stromeyer said that some very wild statements had been made as to the consumption of coal in this country per indicated horse-power. He believed that a Cabinet Minister had stated that it was 7lb. The actual figure, however, was about 2½ or 3lb. In some cases it was more like 2lb. It was from statements of this kind that he believed the country had been misled into hoping to get far greater economies from power schemes than they were likely to get.

Mr. T. Goulden agreed that a survey of the coal fields of the country would be of enormous importance, because it would enable special coals to be used for the best purpose to which they were adapted. Gas manufacturers were great economisers of fuel. They conducted processes which gave an efficiency of not less than 70 per cent., and might reach well over 85 per cent. They not only made the best use of it from the thermal point of view, but they produced sulphate of ammonia and a large number of by-products which were essential to the industries of the country generally. If the percentage of inerts suggested in the Fuel Research Board's report was imposed it would mean that the gas industry would have to carbonise a further 10 per cent. of coal, or 2,000,000 tons, in order to achieve the same result.

Sir Charles Parsons (President of the Association) said that the view of Sir George Beilby, Chairman of the Fuel Research Board, was that the carbonisation of coal had not been successfully attacked on scientific lines. He thought it was far too soon to judge the Fuel Research Board. It was working hard, and he believed that in about a year's time good results would be achieved.

Professor W. H. Watkinson said the country should have some further information as to why the output of coal in this country had decreased and not so in America. He could not believe that it was because of the greater decreased effort of our workmen and the lesser decreased effort of the men of the United States. There must be some other factor upon which we had not been enlightened. He felt that greater economies might be effected by super-gas stations than by super-electric stations, because he believed that the energy required throughout the country could be distributed as economically by gas as by electricity.

Professor H. E. Armstrong, F.R.S., said the subject was such an important one that he regretted that Sir Charles Parsons had not brought it into greater prominence in his presidential address to the Association. They all had the greatest respect for Sir George Beilby, the head of the Fuel Research Board, but there was a strong feeling among chemists that Sir George was keeping the research to himself. It must, however, be made an open one. Sir George Beilby should bring them all together time after time to discuss every issue in this important question so that it could be dealt with properly, and he challenged him to do that. He would also offer that challenge elsewhere. The Fuel Research Board had taken on the research and had then warned everybody else off. That was absolutely unsound. Ideas were not centred in one individual or in one centre. Imagination was needed, and it was never known where it would be found. Coal was a thing of which enormous quantities were required. Lord Fisher had said that the Navy would have to be worked with oil. Where was it to come from? America said that 25 years hence she would have none. We should not find any in this country, but a good deal could be obtained from coal if we were careful. If Lord Fisher's programme was to be carried out it would be necessary to obtain oil from coal in this country, but it could not be done with present methods. The gas industry could not survive as a gas industry producing its own gas, and they knew it. That was why they required a reduced standard. Until the gas industry was combined with a power-producing industry they could not solve the problem of using gas for heating. Nobody would use gas for lighting in the future if they could help it. The gas industry must be combined with an industry that was producing gas as a by-product. Only within the past few months he had seen an experiment carried out with a ton

of coal which gave a most magnificent heating fuel, and, in addition, 18 gallons of tar, 15lb. of sulphate of ammonia, and 8,000 or 9,000ft. of gas. The smokeless fuel amounted to 72 per cent. of the original fuel. A coal of that kind was most valuable, and all that the gas companies would require. There was a great deal of knowledge and experience in this country on this matter, and a great many people were thinking about it. What was needed was to bring competent people together to deal with it. At the present moment it was being done in the very human way of keeping things to themselves. Sir George Beilby was a very reticent type of man, and they had got to force him to be less shy.

The discussion then closed.

CONTINUATION OF RESEARCH WORK.

Before the discussion of the report of the Fuel Economy Committee was commenced on Friday (September 12), the President (Professor Bedson) announced that the committee of the Chemistry Section had passed a resolution suggesting the desirability of continuing the researches on explosives, chemical warfare, and physical and engineering problems bearing on military work.

Sir William Pope said that the present attempt to economise in public expenditure seemed likely to have the effect of abolishing all that had been done during the past five years in the directions indicated.

Professor A. Gray, President of Section A (Mathematical and Physical Science) expressed regret at the closing down of the Inventions Board, and thought it might have been continued on a smaller scale.

The resolution was put to the Section and carried with a few dissentients.

EXPORTS OF CHEMICALS FROM NORWAY.

THE following figures, taken from the Official Statistical Bulletin of Norway of December, 1918, show the exports of chemicals from that country during 1918, in comparison with 1917:

Chemicals.	1917.	1918.
	Kilos.	Kilos.
Nitric acid	1,621,170	836,686
Oxalic acid	334,089	206,028
Sulphate of ammonia	50,000	—
Nitrate of ammonia	63,578,120	49,587,663
Sodium nitrate	22,711,200	2,636,553
Sodium nitrite	3,536,090	2,097,811
Norwegian saltpetre	35,932,400	53,625,250
Cyanamide	2,312,910	10,490
Calcium carbide	46,066,630	41,771,876
Iodine	1,180	5,373

Exports of matches were given as 5,014,918 kilos. in 1918, as compared with 4,044,680 kilos. in 1917; ferrosilicon, 29,449,710 kilos., against 16,861,278; and gunpowder and other explosives 1,130 kilos., against 11,667.

THE INSTITUTE OF METALS.

AN important addition has just been made to the list of papers that are to be presented at the annual autumn meeting of the Institute of Metals, in Sheffield, on Wednesday and Thursday, September 24 and 25. As originally published, the list included nine papers; there are now ten, the latest communication being a note by an American metallurgical engineer, Dr. Zay Jeffries, of Cleveland, Ohio, on "The Micro-Mechanism of the Ageing of Duralumin," a subject of great practical interest to all concerned with the working or use of an aluminium alloy that has played a vastly important part in aeronautical engineering during the war. Dr. Jeffries has come over to this country in order to be able to present his communication in person to the Institute at its Sheffield meeting, at which a record attendance of home and overseas members is assured. Copies of the note are now in the press, and will be forwarded to all members and applicants for membership upon application being made to Mr. G. Shaw Scott, M.Sc., Secretary, Institute of Metals, 36, Victoria Street, S.W.1, from whom also there can be obtained membership forms providing (in the event of success in the forthcoming ballot) for election in time for participation in the whole round of unique technical and social functions at Sheffield.

SCIENTIFIC AND INDUSTRIAL RESEARCH.

PRIVY COUNCIL COMMITTEE'S ANNUAL REPORT.

(Concluded from page 280.)

The Abrasives and Polishing Powders Research Committee.

Important progress has been made during the year in the work carried out under the direction of this committee. An extensive investigation has been made of the polishing of glass by means of ferric oxide, a material selected as the starting point of the research, because it is most commonly used in polishing work, and so most likely to yield results of immediate practical value. Preparations of the oxide have been made by several different methods, and these preparations have been compared as regards their physical properties and polishing powers. In this way much information has been accumulated correlating the methods of preparation, the physical condition, and the polishing effect of the different samples. The practical outcome of the work has been the production, under standardised conditions, of a rouge found by trials on a technical scale to be quicker in action and more satisfactory in general effects than existing commercial rouges.

The investigation having reached a stage at which results of technical value are being obtained, the Advisory Council have thought the time opportune for the transference of the research and the accumulated results and experience to the British Scientific Instrument Research Association. This transference has been effected, and, in continuing the research, the Research Association is employing the services of the investigator who hitherto has had most to do with the practical side of the work. Continuity and full utilisation of the experience so far gained are thus ensured, and it should be possible for the past and future results to be promptly available for the industry primarily concerned.

Copper and Zinc.

There is a large field for research into the metallurgy of copper and zinc, and this is work which will fall to the Non-ferrous Metals Research Association when it comes into being. In the meantime, on the recommendation of the Copper and Zinc Inquiry Committee, the expenditure of £450, to enable survey work to be undertaken has been approved. Information is being collected relating to certain aspects of copper smelting and copper refining, the special requirements to which copper products must conform under working conditions, and the extent to which these requirements have been met by existing products. A reference list is also in preparation of the qualities of copper and copper alloys of industrial importance.

Aided Researches.

Research on refractory materials undertaken by the Institute of Gas Engineers with the aid of a grant from the Department has been continued during the year. Experiments have recently been carried out with conspicuous success on the manufacture of gas retorts, and the results obtained are likely to mark a great advance in this branch of the refractory materials industry. Demonstrations of a new method of casting 5ft. gas retorts have been given before the Institute of Gas Engineers, and a careful examination by the Research Committee of this Institute of the retort produced proved satisfactorily that the process used for its manufacture was thoroughly practicable. This important industrial result has been produced at the cost of a few hundred pounds. In addition, the behaviour of firebricks under conditions similar to those experienced in practice has been investigated, experiments having been carried out on the corrosive action of flue-dust, the refractoriness of fire-bricks under load, and the deterioration of fire-bricks in prolonged use. Researches have also been undertaken on the relation of grain size and different proportions of grog in fire-bricks to such properties as the crushing strength, the contraction, and the thermal conductivity at high temperatures. Other work in progress or in prospect includes the study of binding materials for siliceous bricks and retorts, the specific heat of silica materials at high temperatures, the thermal radiation of refractories, and the study of the effect of reducing atmospheres.

Patents.

The holding of patents by the Government on any large scale undoubtedly raises many difficult questions, particularly if it is sought to protect inventions abroad.

The question of how best to deal with foreign patents is peculiarly difficult. It is a problem in which the Department is as directly interested as the Research Associations. Indeed the question of patenting abroad is a more embarrassing one for the Government than for private or semi-official corporations, for if the Government was itself to hold foreign patents it might easily become involved, if the discovery were a valuable one, in international controversy. The Council gather that the usual practice, in cases where secrecy has not been essential, has hitherto been to allow inventors in the service of the British Government to take out foreign patents in their own names and for their own interest, and to include this right as part of the reward for their discovery, while the British patents may either be vested in the Minister responsible for the Department concerned or otherwise dealt with according to circumstances. But this is obviously not an altogether satisfactory method, for it might well happen under peace conditions that a discovery made in this country would be most advantageously, or indeed exclusively, produced in a foreign land. The difficult question as to the wisdom of calling the attention of foreign countries to a British discovery by applying for a patent having been answered affirmatively, the important question of finance still remains to be faced, for the successful maintenance of a foreign patent may involve the expenditure of large sums of money.

Accordingly, some device seems to be called for, both in the case of Government and of research associations, which would enable foreign patents to be taken out in a wider interest than that of the discoverer, but which would avoid the special difficulties referred to. It may be that different procedures will be necessary for the two cases, but if an organisation could be devised which would deal with both it would undoubtedly be preferable. But it is by no means easy to determine the best procedure in the case of discoveries made with the aid of Parliamentary funds, even when patenting abroad is left out of consideration.

In this country, as in America, there is no central authority entrusted with the duty of holding and administering patents taken out under Government and no agreed uniformity of practice. No worker under this Department may patent a discovery except with the leave of the Committee of Council, and where leave is given the patent is taken in the joint-name of the inventor and the Imperial Trust for the Encouragement of Scientific and Industrial Research. The Department reserves to itself complete discretion in the administration of the patent rights after consultation with the inventor. When a worker, engaged in research under a committee or board of the Department or in receipt of grant from the Department, desires to take a patent he must do so in conjunction with the Imperial Trust, but in these cases the Trust reserves the right to refuse to be a party to the patent. So far the procedure is simple, and it might possibly be extended to other Departments. But at this stage the real difficulties begin. Apart from the embarrassments inherent in foreign patents, a number of special considerations arise before a decision can be reached on the advisability of patenting, for the Government cannot proceed with the single eye to financial advantage which commercial undertakings rightly use.

So far the Advisory Council have provisionally decided that patents should not be taken for (a) inventions of value for the preservation of health or of life, or (b) inventions the use of which can be enforced by a Government Department. In these cases steps are taken to secure full and complete publication with a view to preventing others from securing a patent for the invention. The strong professional tradition of the medical profession in this country has led the Council to refuse patent rights in the first class of case, and there are obvious reasons of expediency for refusal in the second. But they are aware that reasons can be urged for a different practice, and they think they should receive full consideration. American and Canadian opinion leans to the view that the refusal to patent has serious disadvantages, since in the absence of a patent a manufacturing firm has no incentive to work the invention. And there is little doubt that this is true in those cases where the invention needs further development before it can be placed effectively on the market, and in these cases where no effective demand for the invention exists in the absence of an active commercial campaign. Where, on the other hand, a powerful profession can push a new discovery, or where a Government Department can enforce its use, these considerations lose much, but by no means all, of their weight. The whole question needs careful watching and discussion by those best able to form a judgment.

GERMAN DYE FACTORIES IN WAR-TIME.

THOUGH publication of the report of the British Mission which recently visited German chemical factories in the occupied zone has not yet been made here, we learn from *Metallurgical and Chemical Engineering* (New York) that it was introduced at the dyestuffs hearing before the House of Representatives Committee on Ways and Means, in order to emphasise the military value of a well-developed chemical industry. The following data have been taken from this report. In some cases difficulty was experienced in obtaining accurate details of manufacture, especially as regards substances which have a peace value, and the information must be accepted with some reserve on this account, although it was checked by cross-examination of the officials concerned and by a careful examination of the plant admittedly employed for war purposes.

Some years before the war a combination was formed by the Bayer, Badische and A. G. F. A. companies, and somewhat later a second group was formed which included Meister, Lucius and Bruning, Casella and Kalle. During the war these two groups amalgamated, and the Griesheim Elektron, Weiler-ter-Meer, Leonhardt and other smaller companies entered the combination, which is known as the I. G. (Interessengemeinschaft). It was largely owing to the efforts of this combination that Germany was enabled to continue the war in spite of the blockade. The I. G. works produced the bulk of the synthetic ammonia and nitric acid needed for the production of fertilisers and explosives, all the poison gas (with the exception of some chlorine and phosgene), and a large proportion of the high explosives.

The following are the more important works of the I. G. which were not visited, as they are outside the occupied zone: Factories of the Aktien Gesellschaft für Anilin-fabrikation; factories of the Griesheim Elektron Gesellschaft; factory of the Bayer Co. at Elberfeld; factory of the Badische Co. at Merseburg; factory of Casella and Co., Mainkur, near Frankfurt; factory of Leonhardt and Co., Mulheim, near Frankfurt.

A summary of the information obtained as to the war production of the factories visited is given under the headings of "Initial Products," "Explosives and Poison Gases."

TABLE I.—AMMONIA (METRIC TONS NH_3 PER DAY).

Leverkusen	7 ..	20
Hochst	4 ..	8
Ludwigshafen	13 ..	35
Total	24 ..	63

The principal materials concerned are ammonia, nitric acid, sulphuric acid and chlorine, and it was on the output of these that the war production of chemical munitions depended. The expansion of output by the factories of the I. G. combination during the war is shown by Tables I-IV.

Explosives. No arrangements appear to have been made prior to the outbreak of war to utilise the resources of any of the dye factories for war purposes, and on mobilisation their chemists were called up for military service. After the battle of the Marne the Government realised the need for expanding the output of explosives and most of the chemical

works were producing small quantities by the end of 1914. The demands made on them increased during 1915, but it was not until 1916 that plant was laid down to assist in the enormous production of explosives required by the Hindenburg programme. Most of the big extensions of the synthetic ammonia and of the nitric and sulphuric acid plants date from this time, many chemists being released from the army and the scientific staff of some of the works being augmented. Standardised plant used for the manufacture of dyes was converted for the production of explosives with remarkable speed; for instance, at Leverkusen a TNT plant producing 250 tons per month was put into operation in six weeks.

Tables V. and VI. show the amounts produced in the factories visited.

TABLE V.—HIGH EXPLOSIVES AND INTERMEDIATES.

Quantities of intermediates are shown only where these were not converted to finished explosives in the producing works.

(Metric tons per week.)

Factory.	Ammonium Nitrate	Dinitrobenzene	Dinitrotoluene	Trinitrotoluene	Mononitro-naphthalene	Dinitroamph-thalene	Dinitrochlor-benzene	Dinitrophenol	Picric Acid	* Trinitroisole	Dinitrodiphenyl-amine	Hexanitro-diphenylamine

Poison Gas. At first chlorine and phosgene were the main requirements, but afterward a variety of organic substances were employed, all of which were made by the factories of the I. G. combination. Many of these substances were new and difficult to prepare, and rapid production was only possible

TABLE VII.—OUTPUT OF FINISHED POISON GASES FROM VARIOUS WORKS.

	Factory.	Monthly (Metric Tons) Average.	Output (Metric Tons) Maximum.	Total Production (if known) Tons.	Date of Com-mencement.
1. Chlorine	Leverkusen	600	—	—	Prior to war

* Estimated from capacity of plant. Probably the same quantity was produced at some other factory, as the output of thiodiglycol from Ludwigshafen would make for this.

owing to the speed with which the peace organisation of the dye factories could be utilised for this purpose. When the Government wished to introduce a new gas, a conference of the various firms was held at Berlin to determine how the manufacture should be sub-divided in order to use existing

plants to the best advantage. For instance, the initial stages of the manufacture of mustard gas were carried out at Ludwigshafen and the final stage at Leverkusen.

Tables VII. and VIII. show the production of gas and the intermediate products in the various factories visited.

TABLE VIII. OUTPUT OF INTERMEDIATE PRODUCTS FOR POISON GAS MANUFACTURE.

Finished Gas.	Intermediate Products.	Total Output (Metric Tons.)	Place of Production.	Destination of Intermediate Products.
Phenylcarbylamine ..	Phenyl mustard oil ..	(*)	Kalle	Hochst
Mustard gas	Thiodiethylol ..	7,026	Ludwigshafen ..	Leverkusen and 1 other factory
Diphenylchlorarsine ..	Phenylarsenic acid ..	1,600	Ludwigshafen ..	Unknown
		1,200	Kalle	Unknown
	Diphenylarsenic acid	4,800	Leverkusen	Probably A., G. F. A., Berlin
Ethylchlorarsine ..	Ethylarsenious oxide	840	Ludwigshafen ..	Hochst

* Not obtained.

Note. In addition Hochst produced 3,000 tons of diphenylchlor- and cyanog-arsines from own intermediates.

These figures for the output of explosives and gas show the great military value of the factories of the I. G. combination. Although no arrangement had been made to mobilise them at the outbreak of hostilities they were rapidly converted to war purposes, thanks to their highly trained personnel and the great technical resources of their peace organisation. In the future it is clear that every chemical factory must be regarded as a potential arsenal, and other nations cannot therefore submit to the domination of certain sections of chemical industry which Germany exercised before the war. For military security it is essential that each country should have its chemical industry firmly established, and this must be secured as one of the conditions of peace, as otherwise we are leaving Germany in possession of a weapon which will be a permanent menace to the peace of the world.

The key to Germany's war production of explosives was the Haber process for the production of ammonia from atmospheric nitrogen. It is significant that large-scale production by this process only began at the end of 1912, and that in the early part of 1914 great pressure was put on the Badische Co. to increase its output. During the war, owing to the extension of the Haber plants at Oppau and Merseburg, Germany has become independent of foreign countries for her supplies of ammonia and nitric acid, substances indispensable for the manufacture not only of high explosives but also of fertilisers for food production. Without such a process Germany could not have made the nitric acid required for her explosives programme, nor obtained fertilisers for food production after the supply of Chili saltpetre had been stopped by the blockade, and it is probable that she could not have continued the war after 1916. In the event of another war we might be cut off from supplies of saltpetre.

The resources of the German dye industry are of no less military importance. Most of the gases employed toward the end of the war were complex organic substances, none of which had been made previously except in small quantities, and some of which were prepared for the first time during the war. Gas warfare will undoubtedly continue to develop in this direction, and in the future organic substances will be employed which we do not know to-day. The use of gas will always offer great opportunities for surprise in military operations, and the experiences of the present war have shown that rapid production of a new gas is essential if the surprise is to be effective. Any country without a well-developed organic chemical industry will be severely handicapped in this respect.

ELECTRICAL PURIFICATION OF CLAYS.

THE phenomena known as electrical endosmose and cataphoresis, whereby matter in a very finely divided or colloidal state is capable of being influenced by an electrical potential, have been extensively investigated. For instance, when a colloidal solution of arsenic sulphide is placed in a cell and a direct current at a potential of 100 volts passed from suitable electrodes through the solution, the colloidal particles tend after a time to collect round the positive pole, leaving a clear zone round the negative pole.

It is found that nearly all substances if in a sufficiently fine state of division, are attracted either to one pole or the

other. It has also been observed that aggregates of certain fine particles can be dispersed and separated by adding to the fluid in which they are suspended minute quantities of alkali in the case of those particles attracted to the positive pole, and of acid to those which are attracted to the negative pole. Moreover, if the particles are not sufficiently susceptible to the dispersive effect of the added electrolyte, they can be made so by being allowed to absorb some colloid, such as colloidal silicic acid.

This latter discovery has a most important bearing on the clay industry. China clay and ball clay are examples of such aggregates of fine particles, and if a thick slip is made up of the clay and water the addition of small amounts of alkali causes the clay particles to disperse, and the slip, as a consequence, to become much thinner and more mobile, the clay particles remaining in suspension a considerable time and exhibiting vigorous Brownian movement. On passing a current of electricity through such a suspension, the clay particles collect and adhere closely to the anode plate, the water collecting in a zone substantially free from clay, round the cathode. Impurities in the original clay, such as mica, quartz, felspar, and iron compounds, are either unaffected by the electrical potential and settle out, or attracted to the cathode. A means of purifying clay on a commercial scale can thus be evolved from a consideration of the above phenomena, as was shown by the exhibit of raw and purified clays of the Osmosis Co., Ltd., at the recent British Scientific Products Exhibition.

The commercial equipment for such a process consists of a blunger, settling tanks to allow the coarse impurities to settle out of the suspension, and an Osmosis machine composed of a rectangular trough in which is arranged horizontally a cylindrical metal anode surrounded beneath the surface of the slip and at a short distance away from it by a cathode through which, by paddles or other means of circulation, the clay slip is driven. The cylinder is made to revolve slowly, and by means of a scraper the dried purified clay, containing 20-30 per cent. of water, is collected.

The machine not merely collects the suspended clay and frees it from water, but subjects the suspension to an electrical purification as well, for should there still be in suspension with the clay minute particles of mica, iron, and silica that have not had time to settle out in the tank, these are not attracted to the anode, but for the most part remain in the effluent leaving the trough. Consequently, electrically osmosed clay is a purer product than can be obtained by any method of settling or centrifuging.

The improvements effected by the process are:—(1) Pyritic and other forms of uncombined iron are removed. (2) The sintering temperature of the clay is lowered so that a lower kiln-temperature can be employed, with consequent saving of fuel. (3) Clay can be graded into different degrees of fineness. (4) Fireclays can be rendered more plastic and more refractory by this treatment.

Another very important application of cataphoresis is the electrical filter-press. In this press the electrical potential is utilised as a means of driving out the water from suspensions of fine particles; thus, instead of needing pressures running up to 20 atmospheres in some cases where ordinary filtration is used, a head of 14ft. is ample for the purpose in the electrical filter-press. As an instance of the efficiency and speed with which filtering can be accomplished by such a press, a cake of china clay 4½ in. thick containing 25 per cent. of water can be made in less than two hours.

The applications of electrical endosmose or electrical dialysis in various industries is of importance. Gelatine can be freed from all inorganic mineral matter, so that an ashless gelatine can be obtained of a purity which should be suitable for photographic purposes. There is a clear experimental evidence that pure colloidal silicic acid can be prepared from sodium silicate and alumina from sodium aluminate by subjecting their solutions to an electrical potential in cells with suitable diaphragms through which the alkali can migrate. These are a few examples of useful developments, but it is evident that an increasing number of important commercial processes may be expected to arise out of the application of the principles underlying the above phenomena.—*Nature*.

AMERICAN IMPORTS OF POTASH.—The United States War Trade Board Section of the Department of State has issued a further ruling, dated August 7, the effect of which is that potash may now be imported into the United States under licence "P.B.F., No. 37," from all countries except Hungary and Bolshevik Russia.

ITEMS OF INTEREST.

ZINC AND ZINC DUST PRICES.—Australian high-grade zinc dust (88.92 per cent. metallic zinc) remains at £68.£70. per ton, c.i.f., U.K. Australian electrolytic zinc (99.95 per cent purity) is unchanged at £42. per ton, f.o.b. Australia, for direct shipment to New Zealand, India, South Africa and the Far East.

STOCKS OF NON-FERROUS MATERIALS.—The following particulars are published of the stocks (exclusive of old metal and scrap) in this country in possession of the Minister of Munitions on September 1:—Copper, 28,049 tons; spelter, G.O.B., 20,041 tons; spelter (refined), 10,963 tons; aluminium, 10,232 tons; soft pig-lead, 84,057 tons; nickel, 2,374 tons; antimony regulus, 3,386 tons. A proportion of the above stocks is already sold to the trade for forward delivery.

RESEARCH ASSOCIATIONS.—The Glass Research Association, established in accordance with the Government's scheme for encouraging industrial research, has been licensed by the Board of Trade as a company not trading for profit. The secretary is Mr. E. Meigh, 7, Seamore Place, W.1. The Department of Scientific and Industrial Research have approved the Memorandum and Articles of the British Refractories Research Association, which are now under consideration by the Board of Trade. Mr. A. C. Rann, 14, Great George-street, Westminster, S.W.1., will act as secretary of the Association.

GERMAN PRODUCTION OF FERTILISERS.—According to the *Deutsche Allgemeine Zeitung*, the production of certain fertilisers in Germany during 1913-14, 1917-18, and 1918-19, was:

Articles.	1913-14.	1917-18.	1918-19.
	Tons.	Tons.	Tons.
Nitrogen	210,000	92,334	80,000
Phosphoric acid	530,000	325,000	220,000
Potash	557,350	779,400	520,000

FEDERATION OF TECHNICAL AND SCIENTIFIC PROFESSIONAL ASSOCIATIONS.—A meeting of the Federation of Technical and Scientific Associations was held in London on September 6, to which kindred associations had been invited to send representatives. Fourteen associations were present, representing the interests of about 50,000 professional officers and servants. The meeting was presided over by Mr. A. C. J. Charlier, the President of the Federation. The draft proposals for the constitution of the Federation were considered, and many useful suggestions agreed to. It was agreed that all duly qualified bodies as shall accept the constitution and adhere to the Federation by the date of the next meeting, viz., October 18, shall be considered original members of the Federation. It was also decided to form Group Committees for each professional interest represented to advise the Federal Council. At the conclusion of the meeting the representatives of the British Association of Chemists announced their intention to join the Federation, and Mr. N. Wyld intimated that the Society of Technical Engineers would probably become members.

ALLEGED THEFT OF SCRAP LEAD.—At Bow-street Police Court on Tuesday, before Mr. Graham Campbell, Albert Evan Whatcott, 29, general dealer, of Pyrland-road, Canonbury, was charged on remand with stealing 40 tons of scrap lead, valued at £1,291., the property of the Ministry of Munitions. Mr. Travers Humphreys, who prosecuted, said that at the time this matter arose the defendant occupied a high position at the Ministry of Munitions. From September, 1917, the Ministry took possession of all the lead in the country and allocated it to firms engaged on Government contracts, or on work in respect of which a priority certificate had been obtained. The defendant was virtually the head of the department dealing with that matter. After the armistice he proceeded, by an ingenious trick, to obtain a large quantity of lead for himself without payment. He invented a firm which he called the Premier Metal Foundry (Limited), and in that name put forward a requisition for 40 tons of lead, representing that it was required for the use of printers. He passed the requisition to one of his clerks, instructing him to allocate the full amount. The lead was duly delivered to an address in Verulam-street, Gray's Inn-road, and was afterwards sold by the defendant to a Mr. Elias Barnett for about £1,300. A further remand was ordered, the defendant being allowed bail as before in £400.

DYESTUFFS STANDARDS FOR CHINA.—Practical dye men and Hong Kong importers of dyes report that the chief factor in the future of the sale of dyes in China is the standardisation of colour shades. One of the chief elements of the success of German dyes in this field was that certain shades popular among the Chinese could be relied upon. The matter of colour is very important among the Chinese, aside from the comparative beauty. Many of the colours have special significance of a ceremonial sort as well as being regarded as more or less lucky or unlucky. There are large interests in China, especially in Amoy, Swatow, Chuchow, and various South China coast cities, where imported shirtings and sheetings are dyed for sale to the Chinese. The basis of this entire business is the quality of colour in the cloths thus handled, which depends on the uniformity of colour and the quality of the dyes.—*Board of Trade Journal*.

RADIUM AND ATOMIC ENERGY.—At the second day of the James Watt centenary commemoration at Birmingham on Wednesday Sir Oliver Lodge said that, in view of the fact that the sources of molecular energy are beginning to show signs of exhaustion, he ventured to assume that if James Watt were living to-day he would be directing his attention to discovering whether there are other stores of energy at present almost unsuspected. The fact was that contained in the properties of matter there was an immense source of energy so far inaccessible, but which he saw no reason why the progress of discovery should not make available. He referred to atomic energy which, if it could be utilised on an extensive scale, would, he believed, greatly ameliorate the conditions of factory life. Sir Oliver explained that the secret of this power began to be given away when radio-activity was discovered, and said that at present we were hardly at the beginning of its utilisation.

SHALE-OIL WORKERS AND THE SANKEY AWARD.—A conference of the Federation of Shale-Oil Workers was held in Edinburgh on Wednesday to consider the position created by the refusal of the Anglo-Persian Oil Company to apply the terms of the Sankey Award to the workers in the Scottish oil industry. The representatives who met the company in London last week reported on the negotiations which had taken place. The company's representatives proposed that a profit-sharing scheme should be inaugurated, provided the workers were prepared to forgo the Sankey Award, which granted a 2s. a day increase to them. This proposal was refused, and then the company proposed that the present conditions should continue until the end of this year, when a whole review of the question should be given. The company also suggested that the Government might come to their assistance with a subsidy, or a tariff, on imported oils. The Government had not accepted either. The conditions applying to coal workers and miners have for many years past applied to Scottish oil-workers, and so it was unanimously decided to lodge notices to cease work. They take effect in the cases of oil-workers and miners on Saturday week, and with enginemen and boilermen on October 2.

AMERICAN PHOSPHATE ROCK.—On another page appears the announcement of the formation of an Association of American Phosphate Rock Miners for the purpose of developing the European market for American phosphate rock of the grades 70 per cent., 68 per cent. and 68-66 per cent. By means of this Association it is hoped to familiarise buyers with the advantages of the American product, steady the prices, so that the buyer will not need to fear that his competitor will be able to undersell him, minimise as far as possible the excessive costs of competitive selling, and thus assist the buyers in large part to accomplish that which they are already seeking to achieve in the formation of their various Fertiliser Associations. It is desired particularly to point out that there is no thought on the part of the Associated Miners to use their combined power to force up prices. On the contrary, it is their express purpose to fix a price that is fair both to producer and consumer, and such as will lead to the greatest possible consumption of American pebble phosphate. The Association, which has chosen the title of "Florida Pebble-Phosphate Export Association," will negotiate all orders for the product of the member companies, who include all miners of importance in the Florida pebble territory, their output amounting to over 1,500,000 tons in pre-war years. The head office of the Association is at No. 1, Wall-street, New York City, and correspondence is invited. American pebble phosphate, analysing as high as 79 per cent., is now being mined in large quantities, and it is confidently expected that in the near future largely increasing shipments of this grade will also be made to European consumers.

HOLTON HEATH CORDITE FACTORY.

VISIT OF BRITISH ASSOCIATION MEMBERS.

THE members of the Chemistry Section of the British Association visited the Holton Heath Royal Naval Cordite Factory, which occupies some 500 acres of ground between Poole and Wareham, on Thursday (September 11), and the Engineering Section also went there on the following day. It was impossible during such a visit, although it occupied some four hours, to gather the full technical details of the processes in operation at the factory, and we doubt very much if the Admiralty would allow them to be published, or indeed to give facilities for complete description. Nevertheless, some interesting information is available, although it is of a more or less general character. The first point is that the existence of the factory to the general public has been more or less unknown, and certainly it has never been open to visitors before in the way that it was on this occasion. Captain Desborough, the superintendent of the factory, and Mr. W. T. Thomson, the manager, received the party, which was split up into several sections, each of which commenced its tour from a different point, the programme being so arranged that four sections of the factory were visited before tea, and four afterwards.

The Admiralty took over the land in April, 1915, and was producing cordite by the following December. According to figures given during the visit, the number of employees during the war was about 4,000, in equal proportions of men and women, and the output was about 150 tons per week. For a while, after the armistice it was reduced to 35 tons, but is now 50 tons per week. It is contemplated to reduce this, however, and it may be that industrial alcohol will be produced. Dr. Thaysen, whose paper on Bacteriology is referred to elsewhere, is the resident bacteriologist at the factory, and he has been experimenting in this direction. He expressed the view that with adequate organisation the manufacture of power alcohol from mangolds could be achieved at a competitive price from carbohydrates obtainable in this country. Experiments carried out on reclaimed heath land at the factory, and the experience of neighbouring farmers, had convinced him that the land reclaimed would yield an average crop of 24 tons of mangolds, equal to 240 gallons of 95 per cent alcohol. Taking into account the feeding value of fermented mangolds, the prices in his opinion would be about 1s. 8d. per gallon, but if the average crop could be increased to 40 tons per acre, a proposition which he considered feasible, the alcohol could be produced for 11½d. per gallon. For a yearly production of 1,000,000 gallons of 95 per cent. power alcohol it would be necessary to bring 7,000 acres of heath under cultivation.

The Holton Heath factory has been laid out on a circular plan and is divided into (1) acids department; (2) guncotton department; (3) engineering department; (4) acetone recovery department; (5) nitroglycerine department; (6) acetone recovery department; (7) cordite department; and (8) laboratories. Pyrites and nitrate of soda are taken direct from the railway into the acid department, where sulphuric acid is made by the contact process, and nitric acid by a modified silica coil system; sulphuric acid is concentrated by the Kessler system, and sulphuric acid fume is condensed by Cottrell electrostatic precipitation plant. In the guncotton department the visitors were shown cotton bale breaking, tearing, and drying, as well as nitration by the displacement process, whilst the vat house, and pulping, moulding, and pressing, were also in operation. In order to obtain a more stable cordite, the practice of using cheap cotton waste, as at Gretna, is not adopted at Holton Heath, but a form of half-manufactured cotton, and this has necessarily added to the cost of manufacture. The advantages are a matter of controversy, but at Holton the extra cost is regarded in the light of an insurance premium. The engineering department calls for no special comment, although the labour-saving devices attracted much attention.

The acetone department, laid out for the manufacture of acetone and butyl alcohol by a fermentation process from maize, rice, etc., with six fermentation tanks each having a capacity of 150,000 gallons, was standing idle, but it would come into useful operation if the scheme mentioned above of producing power alcohol from mangolds ever materialises. In the nitroglycerine department, of course, were drying stoves. Nitration is carried out by a displacement process, but the nitroglycerine compressor process, the tetryl nitration process, and the tetryl purification process were not in

operation. The recovery of acetone from cordite stoves is carried out by the bisulphite process, and the recovery has reached as much as 60 per cent. We next passed to an inspection of the incorporating and pressing processes in the cordite department, had a view of the men's changing room and women's messroom, and finally visited the laboratories. There are four—viz., the main laboratory, divided into general and heat test laboratories, with a meteorological station; and the acetone laboratory, containing bacteriological and chemical laboratories. Included in the itinerary of the engineers' visit was the service reservoir, which, constructed with brick and concrete, has a capacity of 3,600,000 gallons.

OUR BOOK SHELF.

A TREATISE ON BRITISH MINERAL OIL.—Edited by J. Arthur Greene. London: Charles Griffin and Co., Ltd., 21s. net. (Postage extra).

Well known names are found amongst the contributors to this book, notably, Cunningham-Craig, Ormandy, Mollwo, Perkin, Andrew Campbell, Danstan, and Sealbrooke, etc., whilst the late Sir Boverton Redwood, Bart., supplied a foreword. It will be found that these practical scientists have produced a technical book which will render the greatest possible assistance in the establishment of a new industry of national importance. Although efforts are still being made to locate and develop mineral oil in various parts of the country, it is considered that the cannellaid resources of the country afford the best and most easily utilisable source of supply. The book is confined therefore to extraction from shales and bituminous materials. In the first 63 pages, a very lucid account is given of the characteristics, composition, and location of raw material, the author being distinctly in favour of the canals in their various forms—parrots, torbanites and intermediate deposits. Section 2 contains adequate description of processes and plant involved in the retorting operation according to the latest developments in gas retorts, coke ovens and low-temperature plants. Section 3 is of particular interest and importance dealing as it does with the products of low temperature carbonisation and their chemical nature. Valuable chapters in this section refer to the thermal decomposition of coal, yields from various raw materials, such as lignites, cannel, shale (Norfolk and Kimmeridge, etc.), and peat, a short chapter on their utilisation being included. Section 4 consists of a very practical description of refining processes. The book is liberally provided with important diagrams and illustrations of plant and machinery suitable for large scale work, which combined with its exceedingly valuable text make it a volume of great importance.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

The position is worse rather than better this week. The threat of an ironfounders' strike has had an adverse effect upon the Cumberland hematite pig-iron trade, and demand for ordinary mixed numbers has fallen off. Flat and stagnation in the steel-rail industry have compelled the damping down of a furnace at Maryport, and it is extremely problematical whether it will be lighted again this year. None of the Cumberland coke is used farther south on the North-West Coast than Millem, and as several of the fourteen furnaces in blast are on low phosphorus brands of iron, it is quite evident that the entire output of the 380 by-product ovens, even if they are working at only two-thirds their capacity, cannot be fully absorbed. Stocks are already accumulating in works yards, and unless there is a decided improvement in the iron trade within a week or two, it is clear that a reduction of coking activity will be inevitable. East Coast coke supplies to the blast furnaces are also low this week. To the Furness district they are 14,000 tons, and to West Cumberland 8,000 tons. The make of by-products is naturally being diminished, and the acid plants of the chemical works on the coast are affected. For benzene and sulphate of ammonia there continues to be a lively demand, and pitch likewise remains a strong trade.

CORRESPONDENCE.

*. We do not hold ourselves responsible for the opinions expressed by our correspondents.

Chemists at Gretna Factory.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—I have every sympathy with your correspondent "Muldoon N. 5. W." But why put all the blame on the Ministry of Munitions? Why as a steelworks chemist did he accept a position at £175. per annum? And why, being a chemist, did he work at an unskilled labourer's job? Why bring in the leadburners' large wages as a comparison? I never found them large, and had to keep myself in a hostel and support my wife and family at home, and had no banking account to draw on. The sole reason that the leadburners had larger wages than hillmen and chemists was that the leadburners were for the greater part trained skilled tradesmen who were all organised and members of the plumbers' trade union, and who made it a point of honour to see that the Ministry or any others did not take advantage of their less skilled fellow-tradesmen.

As a workman who has always been interested in the scientific fundamentals of industry—and, though handicapped with a very elementary education, have always striven to know the reason of things,—I would respectfully point out to "Muldoon" and his friends that the chemists at the Gretna Factory had only themselves to thank for the state of affairs there. For the most part they suffered from swelled-headed snobbery, and to such an extent as to bring their profession into ridicule, and to make the very name "chemist" a by-word in the factory. Even the comedians at the local music-halls and concerts played off jokes about the "Gretna chemists." The chemists of Gretna carried this snobbery to such a length as even to affect the same style of dress—viz., soft hat, sports coat, breeches, and leggings. To a man who knows and honours the value of the true chemist, it was a pathetic spectacle.

I place great value on chemistry, and believe it to be the science which will one day explain everything. But this affectation and exclusive snobbery of many present-day chemists wants a hard knock on the head. A chemist, after all, is only a skilled worker. It takes as much study and time to learn to be a good plumber and leadburner as it takes to be a good chemist. Snobbery is ruining our chances of advancement as a nation; it holds back progress, and only creates distrust between class and class, profession and trade. The mandarin of two buttons won't speak on a level with him of one button. Let the chemists show that they are followers of science, get rid of professional snobbery, form a trade union, and demand and get wages adequate for their skilled service; and then they will have no reason to make foolish comparisons.—Yours, etc.,

MORRISON.

(Late of Canada House, Easttriggs).

Leith, September 14, 1919.

LEGAL INTELLIGENCE.**Customs Seizure of Pyrogallol Acid.**

In the Vacation Court on Wednesday the case of Brown v. Buskley was mentioned to Mr. Justice Greer, on an *ex-parte* application for leave to serve notice of motion with the writ for Wednesday next.

Mr. R. A. Wright, K.C., declared that the action was of great importance, both to the plaintiff and to traders generally. The plaintiff carried on business as a chemical manufacturer, and had imported a quantity of pyrogallol acid. It was now lying at the port of Manchester, where it had been seized by the defendant, who was a collector of Customs.

The plaintiff's case was that this seizure was entirely unjustified by law, and was, in fact, an act of trespass. The defendant was acting under a Government proclamation which prohibited the import of a number of goods except by license from the Board of Trade. That proclamation purported to have been made under a section of the Customs Law Consolidation Act, 1876, under which the importation of "arms, gunpowder, ammunition, or any other goods" might be prohibited by proclamation or Order in Council.

The point the plaintiff took was that the section was limited to arms, gunpowder, ammunition, and "similar" goods, and did not apply to pyrogallol acid, which was an ordinary article of commerce.

His Lordship said it was obviously desirable that there should be an early trial, and gave leave to serve notice of motion for Wednesday next.

SIR JOHN CASS TECHNICAL INSTITUTE.

THE new session of the Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C., will commence on Thursday, September 25. The courses of instruction provided are especially directed to the technical training of those engaged in chemical, metallurgical, and electrical industries, and in trades associated therewith. Full facilities are provided for those wishing to carry out work associated with the industries in which they are engaged, or to undertake special investigations and research. The chemistry, metallurgy and physics laboratories are open both in the afternoons and evenings for work of this character. The instruction in experimental science also provides systematic courses in chemistry, physics, and in pure and applied mathematics for the examinations of London University, and in chemistry and metallurgy for the examinations of the Institute of Chemistry. Special courses of higher technological instruction form a distinctive feature of the work of the Institute. Full details of the courses are given in the syllabus of the Institute, which can be had on application at the office or by letter to the Principal.

LEAD-NITRATE HYPOPHOSPHITE DETONATORS.

THOUGH phosphorus has been utilised in various ways in warfare, attempts to use phosphorus and its compounds in the manufacture of explosives have been little successful. The *Chemische Zentralblatt* recently noticed a paper contributed by Edmund von Herz to the *Zeitschrift für das Gesamte Sprengstoffwesen* in 1916. By mixing lead nitrate and lead hypophosphite Herz obtained a highly-explosive complex lead salt, a nitrate and hypophosphite. To prepare this compound a hot saturated solution of lead nitrate containing 331 grammes of this salt is added to a boiling saturated solution of calcium hypophosphite (170 grammes); the mixture is rapidly cooled while being vigorously stirred; white crystals, of a greasy lustre, of lead hypophosphite are then obtained. These crystals are redissolved and 250 grammes of the solution are mixed with a boiling solution of 500 grammes of lead nitrate in 1.5 litre of water; again the mixture is rapidly cooled. When the preparation is successful the double salt $Pb(NO_3)_2 \cdot Pb(H_2PO_3)_2$ is obtained as a granular crystalline powder which is dried at a temperature of 40° or 50° C.; when the salt separates in needles or as a felted voluminous mass, it is less suitable as a detonator. As regards the rate of detonation the proper lead nitrate-hypophosphite comes up to lead azide and surpasses mercury fulminate. Its decomposition liberates a comparatively small volume of gas, 117 litres per kilogramme, whilst lead azide yields 230 litres and mercury fulminate 314 litres of gas, the new compound is therefore not a very efficient primary explosive. But it offers considerable advantages as a material for percussion fuses, being both sensitive and stable and yielding a flame of high temperature. The lead nitrate acts as oxygen carrier in this compound.—*Engineering*.

DYE IMPORTS INTO INDIA PROHIBITED.

THE Government of India have prohibited, with effect from September 6, the import into India, except under licence, of all derivatives of coal tar, generally known as intermediate products, capable of being used or adapted for use as dyestuffs, or of being modified or further manufactured into dyestuffs; all direct cotton colours, all union colours, all acid wool colours, all chrome and mordant colours, all alizarine colours, all basic colours, all subhide colours, all vat colours (including synthetic indigo), all oil, spirit and wax colours, all lake colours, and any other synthetic colours, dyes, stains, colour acids, colour bases, colour lakes, leuco acids, leuco bases, whether in paste, powder, solution or any other form. Consignments shipped on or before September 6 will be freely admitted. Applications for import licences should be addressed to the Collector of Customs at the port through which it is desired to import the goods. It is understood that licences will always be obtainable for dyestuffs and intermediate products manufactured in the United Kingdom.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Nitrate of Soda.—The August shipments from Chili showed an increase not "of" 56,000 tons, as stated through a printer's error in our last issue, but "at" that figure, the official details being: 5,530 tons to Europe, 38,530 to the United States, and 12,030 to "other parts"; total, 56,140 tons, against 20,380 tons in July. The output having been 108,030 tons, there was an addition of 51,890 tons to the stocks on the West Coast, these amounting on the 1st inst. to no less than 1,652,540 tons, compared with 736,330 tons at the corresponding date in 1913 under normal conditions before the war. Tonnage was then plentiful, ensuring the usual large autumn exports, while it is now so scarce that 240s. per ton is offering for steamers to Europe, and only 22,000 tons were "loading" on September 1. The supply of tonnage will no doubt gradually increase, but there can be no material alleviation of the statistical position before next year, and in the meantime some ten millions sterling worth of nitrate are eating off their head at high rates of interest. The outlook is as serious for the Chilean Government as for the producers, the decrease in the revenue from the export duty being about £4,000,000. in the eight months compared with the corresponding period last year; hence the decline in Chilean bonds, the payment of the coupons on which requires large remittances to Europe. The only redeeming feature in connection with nitrate of soda is the enhancement of the selling prices of sulphate of ammonia, to which we will refer next week.

Continental Fertiliser Notes.—At the meeting of the Chemical Manures Factory, Fribourg, the net profit for the 1918 working year was shown to be 120,334 francs. A dividend of 15 francs per share, or about 10 per cent., was agreed on.

The German potash industry, like so many others, has suffered very severely from shortage of wagons. The Potash Syndicate calculates its losses through this cause alone at 44,000,000 marks. Of course, the loss of Alsace-Lorraine has broken up the potash monopoly, although the syndicate derives considerable satisfaction from the retention of the preponderance in the world market. It is held that it would be to the interest of the Alsatian concerns to adhere to the Potash Syndicate instead of competing with it. Referring to the coal question, it is feared that many works will have to stand idle through the winter if fuel is not supplied in sufficient quantity. The director of the Hohenfels and Bergmannsseggen Potash Works observes that a considerable extension of the potash deposits has been discovered southwards of these works, measuring several thousand metres. The quality of the salts is good. Besides Kainit, other salts of varying richness come under consideration. This works alone has developed pure potassium oxide showing 6,500,000 double zentner.

Algerian Phosphate Enterprise Extension.—A report on the mineral reserves of Algeria states that a number of fresh deposits of phosphate of lime will shortly be put up to auction. It is observed in connection with this notice that the Djebel-Ouk deposits are estimated to amount to 800,000,000 tons. One of the beds is 30 metres thick, and a significant statement is made that large quantities of the product when extracted will be used on the spot.

Sulphate of Ammonia to be Scarce in the East Indies.—It is stated that the importation of sulphate of ammonia from Europe, Australia, and Japan into the Dutch Indies is about to be stopped, the result of which will be a scarcity of manures for the Java sugar cultivation in the year 1920.

Sulphate of Ammonia.—Prices here are now fixed for some time ahead, and the only variation that can mature, apparently, is in connection with the export situation. About £25. f.o.b. appears to be the outside limit at present for export quantities. Furthermore, it does not seem that there will be much to export. Demand from farmers here for sulphate of ammonia is now strong and regular, and this has, of course, become a matter of more interest to manufacturers now that home prices are fixed upon a more remunerative level. In America sales of 7,000 tons have been reported recently for export. The export demand there is greater at this time, considering the season, than it has ever been before. The only thing that is checking it at all is lack of sufficient supplies. As has already been reported in these columns, most of the large producers are sold out to the end of September, but second hands appear to be fairly well

equipped to handle a goodly portion of the business, and are filling a number of large orders for spot material.

Basic Slag and Superphosphates.—Basic slag is still good business at unchanged prices. Quotations appear to be certain to go higher shortly, and the demand shows every evidence of outstripping supply. There are also doubts being expressed as to whether there will be a sufficient supply of superphosphate for the next season. At present superphosphate makers will only sell for this month's deliveries, owing to the uncertainty of supplies of raw materials and the increasing cost of manufacture.

Potash.—Some news comes through from time to time about the potash possibilities of Lake Chad, in Central Africa. It is declared that the district is very rich in potash constituents, and that quite large quantities of these are used in the locality so far as the primitive methods of transport will allow. With regard to the American situation, latest reports show that something of a conflict is proceeding. On the one side we have attempts to stimulate public interest in new potash flotations by the publishing of extraordinary stories of big potash profits. In fact, potash appears to have become a sort of counter on the industrial side of Wall Street. To show how far the promotion side of the business is getting away from the real production side, the story is told of the latest potash promotion, with headquarters 2,000 miles away from the scene of its proposed operations, and with none of its organisers having any connection with either the fertiliser or the chemical industry.

Other Fertilisers.—Bone meals are still scarce, especially East Indian. Arrivals from India are waited for, but are not maturing. Prices vary from £15. 15s. per ton downwards. Some dissolved bone compound is said to have been offered at as low as £8. Dried blood and tankage are also being asked for, but cannot be secured in any quantities. Fish guanos of miscellaneous sorts are pretty generally eagerly snapped up wherever they are offered, but prices con- being 3,400 tons to Bordeaux and 3,000 tons to Algiers. A shipment of 4,566 tons left Newport for Bono.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

Some additional mills have been restarted this week, and the output of tinplates in this district is steadily growing. At Llanelly there is a shortage of water, and as this will not be remedied for a few weeks under ordinary circumstances, several manufacturers are introducing sea-water into their factories in order to scour the plates. This experiment is being watched with much interest by members of the trade, and if successful will solve the difficulties always more or less encountered during the summer months at the majority of the works. The export trade is getting back to normal. There were shipped from Swansea 106,856 boxes, and the receipts from the works were 96,839 boxes, leaving the stocks at 193,060 boxes, compared with 18,169 twelve months ago.

The purchase of Messrs. Lysaght's undertakings by a new syndicate is of absorbing interest owing to the fact that the new directors are interested in so many industrial concerns. Mr. Seymour Berry is one of the financial managers of the Anglo-Continental Guano Works, Gibbs Fertilisers, Ltd., and the Avon Manure Company, Ltd., and he takes more than ordinary interest in by-product plants. Mr. Llewellyn is largely concerned in the patent-fuel trade, and is determined to develop this industry on entirely new lines.

All the patent fuel and briquette factories are fully operating, and there is a very pressing demand for the outputs. The foreign trade is providing fresh markets week by week. Continental customers are pleased with the smaller kind of briquettes, and in consequence the supplies are not equal to the requirements. Swansea manufacturers have despatched over twenty cargoes to different ports, the most important being 3,400 to Bordeaux and 3,000 tons to Algiers. A shipment of 4,566 tons left Newport for Bono.

TRADE CATALOGUES.

Messrs. The Aluminium Plant and Vessel Company, Ltd., send their illustrated loose-leaf Catalogue No. 1, which, quite apart from advertising their plant specialities for the chemical industry, contains a vast fund of information of a technical nature. Chemical engineers will find it particularly useful and, in view of the amount of research and pioneer work done by this firm, highly reliable.

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS.

THE following returns, which are taken from the import statistics of the United Kingdom, give the amount and value of chemicals and allied products imported during the month ending August 31, 1919, as compared with August, 1918.

REPORTS OF COMPANIES.

Major and Co., Ltd.

The ordinary general meeting of the company was held at Hull on Friday (September 12), Mr. I. L. Major, chairman, presiding. The Chairman moved the adoption of the report, which stated that, including the amount brought forward, which was practically the same as that for 1917, the profit for the year 1918 was £32,100., an improvement of £4,200. Out of this available sum dividends have been paid on the new six per cent. cumulative preference shares, and 8½ and 10 per cent. on the preferred and deferred ordinary shares respectively, the same as last year. An appropriation has also been made for the reserve for depreciation of £3,500., and of £5,000. for general reserve (making £15,000.), similar to 1917, leaving a carry-forward of £11,800., which the directors estimate is more than sufficient to cover the still unsettled assessment for excess-profits duty. In the course of his remarks the chairman said: I should like to mention a few of the things we are doing. Obviously, my remarks must be guarded. Our solignum wood preserving stain continues to be of world-wide application, and we are entering upon a considerable programme for its development. We are also makers of road material in one of our subsidiary companies. This company has not yet contributed to the profit of Major and Co., but has a very big future. At the other end of the scale we are developing more refined specialities. Our "Pyramid" benzole has a very good name as a motor fuel. We are confining our sales, as far as possible, to a radius of 50 miles from our factories. We are members of the National Benzole Association, which is doing good work in popularising the use of benzole as a motor fuel. I should also like to mention to you that we have been spending considerable sums in research, and have just brought to success in the factory, thanks to the ability and enthusiasm of our chemists, after repeated failures, the production of an article which is required in this country, and which has not hitherto been satisfactorily produced. I should like to take the opportunity of thanking all my associates in the business, both in office and works, for the good work they have put in under very difficult circumstances. We have no complaint to make in our own works of the slackness which one hears so much about in different parts of the country.

Colonel Wellsted seconded the motion, which was carried unanimously.

Magadi Soda Company, Ltd.

The report for the year to December 31, 1918, states that the accounts show a debit balance of £48,954. The sales of the company's products increased at the beginning of the year under review, but the cessation of hostilities and consequent release of soda ash for commercial purposes seriously affected the company's sales of granular soda. Native wages increased to an unprecedented extent, as also did the cost of all material, and this made the hand-winning of the soda uneconomical. It was therefore decided about the middle of this year to discontinue production and devote all the company's energies to the completion of the mechanical winning and transporting plant. The caustic soda plant was brought to the production stage at the end of the year, after delays owing to the difficulty of securing materials and the illness of the manager. Caustic soda of the highest quality is now being produced. The company's claim against the Government for compensation for the use of its railway and water supply by the military authorities in East Africa has been repudiated, and at present remains unsettled. The military authorities are still in occupation of the Irlam works, near Manchester, but no payment of rent has yet been made to the company. In the early part of this year an issue of £500,000. convertible registered debentures was made, and holders of the company's shares on the register were given preferential allotment.

British Portland Cement Manufacturers, Ltd.

Report for the year ended April 30 last states that, including £87,722. brought forward, revenue for year amounted to £345,374. Against this has been charged directors' and trustees' fees, £5,950.; debenture stock interest, £59,506.; debenture stock redemption account, £16,722.; general depreciation reserve account, £75,000.; barge and rolling stock depreciation account and barge insurance, £3,000.; leaving a balance of £185,196. Preference dividend for year absorbed £70,800. Directors recommend dividend on ordinary at rate of 8 per cent. per annum for year, leaving to

be carried forward £91,509. First mortgage debenture stock to amount of £17,970. was redeemed and cancelled during year, making total redemption of this stock to December 31 last £92,322. The desirability of closer working of the company with the Associated Portland Cement Manufacturers (1900), Ltd. (which holds a controlling interest in the ordinary share capital of the British Company), has been recognised by the boards of both companies, who have adopted a scheme of joint management. Reorganisation of the management has been facilitated by arrangements which have been made with the following gentlemen to retire from the board as at July 31 last: Messrs. J. Bazley-White, Robert Brearley, E. S. Curwen, Arthur Durose, A. J. Jack, G. M. R. Layton, Edwin Robson, Leslie G. Shadbolt, Halley Stewart, and C. H. Watson. Messrs. Alfred Brooks and Anthony White, who are managing directors of the Associated Company, have been appointed managing directors of this company; and, on the other hand, Messrs. A. C. Davis and P. M. Stewart have been appointed managing directors of the Associated Company, so that the managing directors of both companies are now identical. A resolution will be proposed at the annual meeting dividing the £10. preference shares into 10 £1. shares.

Yorkshire Dyeware and Chemical Company, Ltd.

The annual meeting was held on September 12, at Leeds, the chairman, Mr. George Bedford, presiding. The report and statement of accounts were approved, and the retiring directors were re-elected. Later, an extraordinary meeting of shareholders took place to pass the resolutions necessary towards increasing the share capital of the company from £75,000. to £150,000., the board's recommendation being that this should be effected by the capitalisation of £75,000. of the reserve fund, and that one new 15s. share be added to every similar share now held. Notices calling a meeting to confirm the proposal will be issued in due course.

American Cyanamid Company, Ltd.

Net profits for the year ended June 30 were \$1,048,752., after providing for war taxes and other charges, and \$1,391,285. was brought forward. Arrears of dividends on the preferred stock up to June 30, 1918, have been paid, leaving \$1,723,529. to carry forward.

Lawes' Chemical Manure Company, Ltd.

The report to June 30 last states that a settlement with the Inland Revenue authorities in respect of the two years ended June 30, 1917 and 1918, respectively, having been reached, the customary accounts for those years are now submitted. Interim dividends of 7 per cent. on the preference shares and 7s. 6d. per share on the ordinary shares have been declared and paid for 1917, and 7 per cent. on the preference shares and 10s. per share on the ordinary shares for 1918, all subject to tax. The accounts for the year to June 30 last show an available sum (including balance from previous year) of £30,930. The directors recommend payment of a dividend of 7 per cent. on the preference shares, less tax, £5,372.; dividend of 10s. per share and a bonus of 2s. 6d. per share on the ordinary shares, both less tax, £15,746.; to reserve for bad debts and doubtful debts, £300.; carried forward, £9,512. A sum of £6,700. for depreciation has been written off in the accounts for the year. Owing to the general scarcity of materials, it has been possible to effect only such temporary repairs to buildings, plant, and machinery at works as would enable manufacturing operations to be carried on, more thorough repairs being performed deferred. Substantial sums have been set aside for this purpose.

United Indigo and Chemical Company, Ltd.

The accounts for the year to June 30 show a net profit of £50,272., and £29,054. was brought in, making £79,326. Further dividend of 15 per cent. on both the preference and ordinary shares, making the usual 20 per cent. for the year; setting aside £14,000. for excess profits duty, and carrying forward £43,324.

DIVIDENDS.

BRITISH ALUMINIUM COMPANY, LTD.—Directors have declared dividend at rate of 8 per cent. per annum, less tax, on ordinary for six months ended June 30, 1919, and dividend at rate of 6 per cent. per annum, less tax, on preference for six months ended June 30, 1919, both payable October 1.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

Canada.

A firm of manufacturers' agents in Toronto are desirous of obtaining agencies for United Kingdom manufacturers of glues, enamels, paints, dyes, etc., for the Province of Ontario. (Reference No. 595.)

Mauritius.

Two inquirers from Port Louis, who are at present in this country, desire to commence an agency business, in partnership, on their return to Mauritius, and they wish to get into touch with United Kingdom manufacturers of motor spirit, lubricating oils, paints, etc. (Reference No. 604.)

Italy.

A produce broker and commission agent in Genoa, established for 30 years, and having extensive connections in the trade, desires to obtain agencies for United Kingdom exporters of cinnamon bark and palm oil. (Reference No. 615.)

Spain.

A Spanish merchant of Saragosa desires to get into touch with United Kingdom firms supplying asbestos, lubricators, paints, and varnish. (Reference No. 620.)

A British merchant of Cartagena is desirous of securing an agency in that city for the sale of tinplates. (Reference No. 621.)

Switzerland.

A firm at Bâle wishes to secure the sole representation in Switzerland of United Kingdom manufacturers and exporters of metals and chemicals. (Reference No. 625.)

Holland.

The Ver. Bureau voor Handelsinlichtingen (Office for Foreign Relations), Amsterdam, states that a Dutch manufacturer of paints wishes to represent an English manufacturer of white lead, lead minium, and zinc white. The Bureau will be pleased to place readers interested in touch with the firm in question.

GAZETTE NEWS.

LIMITED COMPANIES. — Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Aber-lynn Zinc Mines, Ltd.—Resolved August 19, confirmed September 2: That on account of the sale of the assets of the company to Aber-lynn, Ltd., the Aber-lynn Zinc Mines, Ltd., be wound up. H. Boot, 7, Victoria Street, S.W., liquidator. Meeting of creditors at liquidator's, September 23, at 3 p.m. All claims must be sent in on or before that date.

Aladdin Cobalt, Ltd.—Resolved August 20, confirmed September 5: (1) That the scheme referred to in the directors' circular, dated August 11, 1919, and submitted to this meeting, be and the same is hereby approved; (2) that with a view to carrying same into effect the Aladdin Cobalt, Ltd., be wound up. F. F. Fuller, 638, Salisbury House, E.C., chartered secretary, and another, liquidators; (3) that said liquidators be and are hereby authorised to consent to the registration of a new company, to be named the Kirkland Lake Proprietary, Ltd., or some other suitable name.

Baku Russian Petroleum Company (1909), Ltd.—Resolved August 8, confirmed September 1: That it is desirable to wind up the company, and, accordingly, that the company be wound up. J. W. Creasser, 48, Cannon Street, E.C., liquidator. Meeting of creditors at liquidator's September 17.

Copal Varnish Company, Ltd.—Resolved August 18, confirmed September 3: That the company be wound up. J. S. Walker, 41, Jermyn Street, S.W., chartered accountant, liquidator.

Premier Oil and Pipe Line Company, Ltd.—Resolved August 11, confirmed August 27: That it is desirable to reconstruct the company, and that the scheme of arrangement sanctioned by the Court on July 22, 1919, be carried into effect, and, accordingly, that the company be wound up. H. J. de C. Moore, liquidator, who is authorised to consent to the registration under the said scheme of a new company, to be named the Premier Oil Company, or some other similar name.

African Oilfields Syndicate, Ltd.—Meeting of creditors, 10, Coleman Street, E.C., September 15.

Bibi Eibat Oil Company, Ltd.—Resolved August 12, confirmed September 1: That it is desirable to wind up the company, and, accordingly, that the company be wound up. H. W. West, Worcester House, Walbrook, E.C., liquidator. Meeting of creditors at liquidator's, September 18.

European Oilfields Corporation, Ltd.—Resolved August 11, confirmed September 1: That it is desirable to wind up the company, and, accordingly, that the company be wound up. H. W. West, Worcester House, Walbrook, E.C., liquidator. Meeting of creditors at registered office, Worcester House, Walbrook, E.C., September 18.

San Salvador Spanish Iron Ore Company, Ltd., London, E.C.—Resolved August 8, confirmed August 29: That it is desirable to reconstruct the company, and, accordingly, that the company be wound up. E. Wakefield, 89, Bishopsgate, E.C., liquidator, who is authorised to consent to the registration of a new company, to be named the San Salvador Spanish Iron Ore Company (1919), Ltd.; and that the draft agreement submitted to this meeting and expressed to be made between this company and its liquidator is hereby approved, and that the liquidator is hereby authorised, pursuant to Section 192 of the Companies (Consolidation) Act, 1908, to carry the same into effect with such (if any) modifications as liquidator may think expedient.

NEW COMPANIES.

Scottish Oils, Ltd.—Public company. Capital £4,000,000., £1 shares. Objects: To acquire all or any of the ordinary shares of the Pumphreston Oil Company, Ltd., the Broxburn Oil Company, Ltd., the Oakbank Oil Company, Ltd., Young's Paraffin Light and Mineral Oil Company, Ltd., and James Ross and Company, Philpstown Oil Works, Ltd.; to acquire the goodwill, so far as they relate to Scotland, of the businesses of the British Petroleum Company, Ltd., and the Homelight Oil Company, Ltd., and certain of the assets in Scotland of the last-mentioned two companies; and to undertake all or any of the liabilities in connection with the businesses in Scotland, and generally to carry on the business of dealers in and producers, importers, exporters, miners, distillers, refiners, and distributors of petroleum and other mineral oils, oil shale, natural gas, asphalt, bitumen, naphtha, ozokerite and minerals, etc.. Solicitor: William Craig, 190, St. Vincent Street, Glasgow. No notice of situation of registered office was filed at the time of incorporation. The number of the Edinburgh file is 10,612.

Victoria Industrial Laboratory, Ltd.—Private company. Capital £1,000., £1. shares. Analytical, consulting, and manufacturing chemists, dealers in chemicals, drugs and apparatus, utilisers of waste, etc. Registered office: 36, High Street, Chorlton-on-Medlock, Manchester.

Henry Hematite Iron Ore Company, Ltd.—Private company. Capital £25,000., £1. shares. Miners, metallurgists, treaters of by-products, etc. Registered office: Old Bank Chambers, Pontypriid.

Apex Trinidad Oil Fields, Ltd.—Capital £200,000., £1. shares. Agreement with the Anglo-French Exploration Company, Ltd., and the British Borneo Petroleum Syndicate, Ltd. Solicitors: Holmes, Son and Pott, Capel House, E.C.

Spitzbergen Minerals, Ltd.—Capital £60,000., 5s. shares. Registered office: 4, Tokenhouse Buildings, E.C.

Domestic Science Wares, Ltd.—Private company. Capital £1,000., £1. shares. Object: To acquire the business carried on at 91, Duncan Street, Bradford, as "Galloway and Pullan," and to carry on the business of manufacturers of and dealers in soap, polish, paint, oil, varnish, inks, gums, etc.

Houghton, Winterbotham and Co., Ltd.—Private company. Capital £10,000., £1. shares. Coal merchants and exporters, colliery agents and proprietors, ironmasters, steel-makers and converters, manufacturers of and dealers in coal by-products, chemical manufacturers, etc. Registered office: 40, High Street, Tonbridge, Kent.

Pendleton Oil and Chemical Company, Ltd.—Private company. Capital £3,000., £1. shares. Registered office: 5, Lower Gold Street, Pendleton, Salford.

Peall, Roy and Co., Ltd.—Private company. Capital £20,000., £10. shares (500 preference). Object: To take over the business of gun merchants, washers, grinders, and cleaners now carried on by J. W. Roy at 5 and 6, Barb Court, St. Mary Axe, E.C., and Ashgrove Works, Middlesex, as "Peall, Roy and Co."

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

The specifications of the following applications are not printed by the Patent Office until the complete specifications have been accepted.

September 8th to 13th (inclusive).

- Filter-bag Cleaning-devices. Beth, W. F. L. 22,128.
Alloys of Copper. Boever, A. 22,296.
Catalysing-material. British Thomson-Houston Co. (General Electric Co.). 22,076.
Reducing Viscosity of Cellulosic Solutions. Carlsson, O.; and Thall, E. 22,187.
Cyanide Derivatives of Alpha-halogenated Acids. Carpmael, W. (Farbenfabriken vorm. F. Bayer and Co.). 22,467.
Production of Dialkylbromoacetylureas. Carpmael, W. (Farbenfabriken vorm. F. Bayer and Co.). 22,468.
Preventing Loss of Gas when Feeding Solids into Liquids for Generation of Gas. Chapman, P. L. 22,224.
Converting Blue Billy into High-grade Iron. Coles, S. O. Cowper. 22,598.
Complete Extraction of Naphthalene from Gas. Deguide, C.; and Marbais, D. 22,544.
Polymerised Compounds from Unsaturated Hydrocarbons. Dunham, H. V.; and Hall Motor Fuel Co. 22,095.
Recovering Ammonium-aluminium Sulphate from Aluminium-sulphate Solutions Containing Ferric Oxide. Gans, R. 22,079.
Manufacturing Soap. Gans, R. 22,080.
Treating Peat, Brown Coal, etc. Goskar, T. A.; and Thomas, G. E. 22,054.
Desulphurising Sulphur-bearing Hydrocarbons. Hall Motor Fuel, Ltd.; and McCrae, T. A. 22,094.
Apparatus for Drying Peat. Hamilton, R. 22,018.
Electrolytic Cells for Deposition of Metal from Solution. Harris, W. E.; Williams, T. M.; and Metals Extraction Corporation. 22,541.
Purification of Sulphur. Hood, J. J. 22,082.
Manufacture of Acetic Acid. Matheson, H. W. 22,166.
Apparatus for Froth-floatation Process. Minerals Separation, Ltd.; and Wood, L. A. 22,370.
Apparatus for Precipitation of Copper. Nicholson and Sons, J.; and Wyld, W. 22,134.
Electrodes for Electric Furnaces, etc. Norske Aktieselskab for Elektrokemisk Industri Norsk Industri-Hypotekbank. 22,068.
Measuring Predetermined Quantities of Liquids. Reinhard, R. 22,102.
Catalytic Processes for Preparing Acetic Acid from Acetylene. Soc. des Acières et Forges de Firminy. 22,462.
Removal of Free Fatty Acids, Deodorising and Refining Oils and Fats. Vakil, K. H. 22,159.
Purifying Beeswax. Willis, L. H. 22,455.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 6d. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.O.

1917.

- Alkali Percarbonates. Wade, H. (Deutsche Gold- and Silber-Scheideanstalt vorm. Roessler). 11,954. 131,930

1918.

- Recovery of Volatile Solvents Used in Manufacture. Biegeat, J. H. 5,240. 131,938
Oxidation of Ammonia. Partington, J. R.; and Rideal, E. K. 6,112. 131,942
Removal of Sodium Sulphate from Solution. Freeth, F. A.; and Cocksedge, H. E. 8,986. 131,956
Salts of Amido Organic Substances. Morris and Co., H. N.; and Morris, H. N. 9,257. 131,957
Production of Cyanides. Testrup, N.; and Techno-Chemical Laboratories. 10,931. 131,964
Sulphonic Acids. Gibbs, H. D.; Ambler, J. A.; and Selden Co. 11,196. 131,970
Aromatic Nitro-compounds. Gros et Bouchardy, F.; and Perruche, L. J. J. 12,454. 131,982
Treatment of Zinc Solutions Preparatory to the Recovery of Zinc by Electro-deposition. Electrolytic Zinc Co. of Australasia Proprietary. 13,368. 131,998
Smelting-furnace. Dehn, F. B. (National Lead Co.). 14,246. 132,023
Platinised Asbestos. Erabetti, G. 14,325. 132,051
Continuous Process for the Preparation of Monochloro-acetic Acid Starting from Trichlorethylene. Compagnie des Produits Chimiques d'Alais et de la Camargue. 14,513. 132,042
Washing Coal and Concentrating Ores. Chance, T.M. 14,645. 119,038
Apparatus for Enabling Extracts, Infusions, or Decoctions to be Obtained in a Continuous Manner. Kestner, P. 15,408. 132,075
Electric Resistance Furnaces for Heating Gases. Simon, J.; and Sarron, P. F. 15,542. 132,080
Apparatus for Catalytic Reactions. Calvert, G. 18,632. 132,120
Production of Alumina from Clay. Norske Aktieselskab for Elektrokemisk Industri Norsk Industri-Hypotekbank. 19,427. 122,623

1919

- Carbonaceous Materials Suitable for Use as Filtering-media. Wetter, J. (Weinrich, M.). 2,437. 132,164
Separation of Extracted Liquor and Remelted Syrup in Direct Remelting Centrifugal Machines. Lemoine, J. L. 12,344. 132,212
Insecticides. Speyer, E. R. 12,556. 132,214

COMPLETE SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

1919.

- Manufacture of Resin. Koppers Co. 15,680. 132,229
Electric Furnace. Piquerez, E. 18,004. 132,232
Substituting Halogens for the Amino Groups in Amines and Salts of Amino Acids. Chemische Fabrik Flora. 20,863. 132,245
Process of Evaporating Liquids. Krause, G. A. 21,553. 132,256
Flotation Separation of Mineral Substances. Palmer, T. H.; Seale, H. V.; and Nevette, R. D. 21,608. 132,260

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Azides. W. R. Hodgkinson, Woolwich. British Patent, 129,152, of 1918.

An insoluble azide is produced by diazotising a hydrazine salt in practically neutral solution and in presence of a salt, such as silver nitrate, adapted to produce the insoluble azide. The azide is then treated with a solution of a salt such as sodium chloride to obtain the desired azide and an insoluble silver salt. From the sodium azide, other azides, such as lead azide, may be obtained by double decomposition in the known manner.

Dyes. G. B. Ellis, London. (A communication from Chemical Works, formerly Sandoz, Basle, Switzerland.) British Patent, 129,182, of 1918.

Sulphuretted dyes are obtained by heating with alkali polysulphides mixtures of *p*-amino-*p*'-oxydiphenylamine or its homologues or derivatives or the corresponding indophenols with non-hydroxylated *p*-nitroamino benzene compounds. Examples are given of the preparation of dyes from mixtures of phenyl-*p*-amino-*p*'-oxydiphenylamine and *p*-nitraniline, *p*-oxy-*p*'-amino-*m*'-methyldiphenylamine and *p*-nitraniline, phenyl-*p*-amino-*p*'-oxy-*m*'-methyldiphenylamine and 2 : 6-dichloro-4-nitraniline, dimethyl-*p*-amino-*p*'-oxydiphenylamine and *p*-nitraniline; *m*-nitro-*o*-tolidine, *p*-nitrodiethylaniline, and *p*-nitraniline-*o*-sulphonic acid are also specified as parent nitroamines. The products dye cotton blue shades from alkali sulphide baths.

Recovering Volatile Solvents. R. A. Craig, Sir R. Robertson, J. I. O. Masson, and A. A. Drummond, Research Department, Royal Arsenal, Woolwich. British Patent, 129,024, of 1917.

To recover ether vapour from air which has been used in such operations as drying smokeless powders, the air is saturated with alcohol vapour, and the whole of the vapour condensed by bringing the air in contact with liquid alcohol. The vapour-laden air may be passed through a packed tower such as is described in Specification 25993/01, down which flows alcohol cooled to 0° C.: the remaining alcohol vapour may be condensed by cold water, acid, or brine in a second tower. A series of towers may be used, in which case the alcohol need not be cooled.

Thermo-aluminic Mixtures. C. Vautin and Thermalloy, Ltd., London. British Patent, 129,046, of 1918.

Thermo-aluminic mixtures are prepared in the form of a solid body containing free sulphur. A mixture may be made by heating sulphur to not more than 200° C. and stirring in a finely divided metal such as aluminium, or by heating a mixture of sulphur and metal until it becomes plastic, and casting the product. Instead of sulphur, there may be used a mixture of sulphur and a sulphide, preferably pyrites, which mixture has been heated until plastic, cooled, and powdered. Other mixtures consist of an ordinary aluminic mixture of aluminium and iron oxide, together with a mixture of aluminium and sulphur. In each case the aluminium may be pure, or with the usual zinc adulteration.

Nitric Acid and Ammonium Sulphate. A. T. Cocking and Kynoch, Ltd., Witton, Birmingham. British Patent, 129,305, of 1917.

Ammonium nitrate is heated under reduced pressure with excess of sulphuric acid, preferably waste nitration acid, to obtain nitric acid and ammonium sulphate. The latter remains as acid crystals or in solution in the excess of acid according to the quantity of acid employed. The process may be continuous. The excess of acid may be neutralised by ammonia if neutral sulphate is required; or, if a large excess of acid has been used, the solution may be used to treat phosphates for the production of fertilisers.

GLASGOW CORPORATION.—At a recent meeting of the Glasgow Corporation Gas Committee there was submitted correspondence which had taken place between the general manager and the United Alkali Company, Limited, regarding the Corporation's production of spent oxide and the proposed

erection by the department of a sulphuric acid plant, and requesting the Committee to receive a deputation of representatives from the Glasgow and District Sulphuric Acid Makers relative to this matter. It was agreed to receive such a deputation.

MARKET REPORTS.

FRENCH CHEMICAL MARKET. PARIS, Sept. 13.

Business has been quite active since the holidays in the middle of August and the demand in most chemicals is steady. The home industry is still hampered seriously on account of railways and port congestion, lack of coal, etc. The situation of labour has, however, improved to a great extent, and as soon as transport can be resumed on a normal scale industry will be busy and prosperous. In regard to transactions with England, the question of exchange is still all important, and it is most important for both sides to cope with the actual unfavourable situation, so as to render normal business possible. Market conditions have become more settled, as Government and private owned stocks are gradually diminishing, and war time industries are turning again towards normal purposes. Mineral acids are in good demand as previously. Sulphuric acid is freely to hand in as far as transport is possible, but hydrochloric acid is quite scarce. Available lots have been sold at high prices. Phosphoric acid is also scarce, whereas stocks of nitric acid are still extensive. Amongst organic acids, there has been a fair inquiry for oxalic, lactic, and formic acids. Alum is scarce and very firm, though import of Italian potash alum has largely supplied the lack of ammonia alum. Sulphate of alumina has met also with a good demand, and the previously existing stocks are now greatly reduced. Prices remain unchanged. Ammonia and its compounds (carbonate, muriate, and lump salarmoniac) are in fair request, prices are stiffening. Chloride of barium is rather dull, and further reductions in prices are anticipated. Natural carbonate of baryta is at a total standstill, as French sulphate of baryta is freely to hand. Nitrate of baryta is also very quiet, as well as most other barium and strontium salts. The previous large demand for borax and boric acid has somewhat slackened, and the abnormally high prices are likely to drop in the near future. Copper sulphate is active, with the start of the season, but until now prices kept at a low level—viz., 115 frs. per 100 kilos., c.i.f., Atlantic port, equal to £33. per ton. Bleaching powder remains scarce and very active at the unchanged prices of 50 frs. per 100 kilos., delivered free buyer's station, about equal to £12. per ton, c.i.f. Channel port, but rather important quantities have been imported from England and Belgium, even at higher figures. Chloride of calcium has been also imported from Belgium at exceptionally low prices, but business has remained quiet. The home production of precipitated carbonate of lime has been steadily increased and is now in a position to cope with the inland requirements; the price is to-day 75 frs. per 100 kilos., delivered Paris, equal to £17. per ton, c.i.f. channel port. Business has been normal in green copperas, which is valued at 17 frs. per 100 kilos., on rail works. Magnesia compounds (sulphate, carbonate, chloride) have been fairly active, the demand being very good in commercial epsom salts. Notwithstanding the scarcity, import from England has been checked on account of the high rate of exchange. Mercury is freely to hand, and stocks are large. Price is unchanged and remains at 23.50 frs. to 24 frs. per kilo, spot Paris. Phosphate of soda is quiet and the demand for phosphate of ammonia is weakening. White sugar of lead is also quiet at unchanged prices. Minium and litharge are in fair request and white lead is again in strong demand, at high prices. All potash salts are scarce and in great demand, mostly metabisulphite, chloride, carbonate, permanganate of potash, etc. The situation remains, however, as uncertain as before. Soda ash is freely to hand, whereas bicarbonate of soda is scarce. Some quantities have been imported from England, notwithstanding the high rate of exchange, but there is only demand for bicarbonate packed in kegs and no buyers are to be found for bags. Sulphur is again active at unchanged prices. Zinc compounds are somewhat firmer. Chloride has met with some request and sulphate of zinc has become rather scarce. Home manufacturers are very busy, as the actual rate of exchange does not allow free import from England.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London 90%, 1s. 10d. to 2s.; North, 1s. 8d. to 1s. 9d.; 50%, 1s. 10d.; North, 1s. 8d. to 1s. 9d. naked. Carbolic acid, crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 9d. to 9½d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch, 77s. 6d. to 80s.; East Coast, 67s. 6d. to 75s., f.o.b.; West Coast, 60s. to 65s., f.a.s. Solvent naphtha, naked, London, 90-190%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-160%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthaline, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 6d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid, 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b., other ports. Sulphate of ammonia; home trade, September, £19. 10s. per ton; October, £20. 10s. basis 24½%. Nitrate of soda, £22. to £22. 10s.

FERTILISER MATERIALS.

LIVERPOOL, THURSDAY.

Nitrate of soda is firmer, and to-day's quotation for 95-96% quality is £21. 2s. 6d. per ton, net cash, f.o.r. Liverpool, prompt delivery. East Indian bone meal: Owing to rise in the silver exchange with India, the value of this material has considerably advanced, and the quotation for October-December shipment is now £17. 10s. per ton, net cash, ex ship Liverpool, for 4½% ammonia and 52% phosphate of lime. On spot, Liverpool, holders ask £16. per ton, net cash, for 4½% and 45% quality. Mineral phosphates are without alteration, and values at present are only nominal. Dried blood is scarce, the value being about 30s. per unit of ammonia per ton.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £101. to £101. 5s. cash; £101. 15s. to £102. three months; electrolytic, £110. to £123. Tin: Standard, £289. to £289. 10s. cash; £279. 5s. to £279s. 10s. three months; Straits, £289.; English, £284. Lead: Soft foreign, £25. 15s.; English, £26. 15s. Spelter, £41. 10s.; hard, £28. to £30. Antimony, English regulus, 90%, £45. Aluminium £150. Nickel £205. delivered, packages extra. Quicksilver £23. 10s. to £24. Bismuth 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

There is considerable activity in almost all branches of the chemical trade, both for home and export, and values all round are steady. Quotations for caustic soda are unaltered at recent rates, and refined bicarbonate of soda is firm at £7. 10s., in bags; 58% alkali is easy at £6. 15s. per ton, ex store, for spot resale parcels. Bleaching powder dull and unchanged at £15. per ton, softwoods, f.o.r., and £14. for hardwoods, f.o.b. Chlorate of soda is in more request at 6½d. per lb. Potash slow at 1s. per lb. Makers' quotations for bichromates remain as for some time past. Roasted salt-cake firm at 60s. per ton, carriage paid. Recovered rock sulphur £17., in bulk, on rails. Sulphate of copper continues inactive, and quotations nominal for export at £42. f.o.b. Commercial hyposulphite of soda dull at £16. 10s. on rails. Phosphate of soda steady at £26. per ton. Concentrated sulphide of sodium, 60-65%, firmer at £20. per ton in casks. White powdered arsenic still in short supply, and £60. quoted for small spot lots. Yellow prussiate of potash steady at 1s. 9d. per lb.; imports are still prohibited. Soda scarce and dearer at 9d. per lb. Lead salts are in fair demand. English white acetate at £83. and brown £69. per ton. Nitrate slow of sale at £56. per ton. Acetic acid and acetate of soda are unchanged. Brown acetate of lime firm at £11. per ton; grey, £17. per ton; miscible wood naphtha, quiet at 10s. per gallon. Nitrate of soda is firm on the spot at £60. per ton. Green copperas is only moving off slowly, and price easy. Oxalic acid in moderate request at 1s. 2½d. per lb. delivered.

SWANSEA MARKET REPORT.

THURSDAY.

Timplate prices keep firm and are between 36s. and 37s. per standard box f.o.b. Copper transactions are not so brisk, and prices are somewhat irregular. Prompt delivery £100. 5s., and three months £100. 15s. Tin is selling more freely, with an upward tendency owing to reduction of stocks, at £285. 10s. per ton prompt and £280. at three months. Lead prices very steady, with fair sales at £25. 5s. per ton prompt for Spanish, with extra 10s. per ton at three months; English, £26. 10s. Spelter prices have hardened, spot being £40. 15s., and forward £41. 15s. Zinc sheets, English, £64. 5s. per ton; and American £65. f.o.b. at New York. Silver 61½d. per ounce. Aluminium £150. per ton. Antimony remains nominal, with English regulus 90% at £45. Nickel £205. with free delivery to London or equal. Quicksilver, £23. 12s. 6d. per bottle. Pitch remains scarce on strong demand, and prices have further advanced to 60s. per ton f.o.b. Arsenic quiet, with white powdered at £54. 10s. per ton in bags f.o.b. Oxalic acid in better demand at 1s. 2½d. per lb. Sulphate of copper quiet at £42. to £43. per ton in casks f.o.b. less 5 per cent. Sulphate of ammonia steady at £19. 10s. prompt and £20. 10s. forward. Nitrate of soda quiet and steady at 21s. 6d. per cwt. in bags. Turpentine 129s. per cwt. Green copperas quiet, and price further reduced to £3. 17s. 6d. per ton.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

The demand for the heavier chemicals has been well maintained, and a very fair inquiry for some of the lighter products has been experienced. Inquiries from abroad have come in more freely, and have been taken as indicating a more settled state of things. Bleaching powder has been in moderate request and is now readily obtainable. The price is higher. It is £17. per ton, free on rail or conveyance, in buyers' packages. Chloride of calcium has again met with a fair inquiry, and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has been well inquired for, on export and on home trade accounts. Values are: £24. per ton for 76%; £22. per ton for 70 to 72%; and £19. per ton for 60 to 62%. Nitrate of soda has been quiet, and the price is somewhat lower. It may be given as £20. 10s. to £21. 10s. per ton. Saltcake has been in good request, and is £6. 10s. per ton, in casks, f.o.b. Soda crystals have been more inquired for, and are £5. 10s. per ton, in 2cwt. bags, f.o.r. at works. Bicarbonate of soda has been steadily called for, and is £7. 5s. to £10. per ton, according to terms of delivery. Borax has been in rather active inquiry, and English is still scarce. American has been offered, but the prices quoted for it have been too high to induce much buying. Prices of English are: ordinary, £42. per ton; powdered, £44 per ton, in bags. Ammonia alkali has sold freely, and is £6. to £6. 5s. per ton, f.o.r., at works. Hyposulphite has been more inquired for, and is £17. per ton for ordinary, and £22. per ton for pea crystals, in 1cwt. kegs. Sulphite of sodium has been in limited demand, and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals, in 1cwt. kegs. Bichromate of soda has had a quietly steady sale, and is 9d. per lb. Phosphate of soda has been but little called for, and is £25. per ton. Sulphide of sodium has been quiet, and is £20. per ton in casks, and £22. per ton in drums. Chlorate of potash has been more in demand, and is 1s. to 1s. 2d. per lb. Permanganate of potash has had a quietly steady sale, and is 3s. 3d. to 3s. 6d. per lb. Sulphate of potash has been very quiet, and is £40. per ton. Carbonate of potash has been in fair demand, and is £90. to £95. per ton for 80 to 85%. Caustic potash has been in good request, and is £110. to £120. per ton. Nitrate of potash has been more inquired for, and is £55. to £60. per ton for refined, and £40. per ton for ordinary. Canadian potashes have been inactive. Montreal first quality are £210. to £220. per ton, and second quality, £190. to £210. per ton. Bichromate of potash has been in fair request, and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been rather more inquired for, and is 1s. 9d. to 1s. 10d. per lb. Salammuniac has been in quietly steady demand, and is £80. per ton for lump, £75. per ton for seconds, and £5. per ton extra for ground. Sulphate of ammonia has been quiet, and is £19. 10s. per ton for September; £20. 10s. for October; £20. 15s. for November; £21. for December; £21. 7s. 6d. for January, 1920; £21. 15s. for February; and £22. per ton for March to May, 1920. Carbonate of ammonia has been rather more in request, and is 6½d. per lb. Muriate has been but little called for, and is £45. to £50. per ton, according to quality. Magnesia has

been in fair request. Carbonate is cheaper. The price may be given as £2. 10s. per cwt. Sulphate is £10. to £16. per ton, according to grade. Alum has been much inquired for, and is still scarce. It is £18. 10s. per ton for the home trade, and £18. 10s. to £19. 10s. per ton for export. Aluminoferric has been but little in request, and is £8. 10s. to £12. per ton, according to quality. Sulphate of alumina has been in quietly steady demand, and is £12. to £17. per ton according to grade. Sulphur has been well inquired for, and flowers are still in light supply. English kinds are: Flowers, £32. per ton; roll, £28. per ton; and rock, £22. per ton, in bags, f.o.r. Sicilian grades are: flowers, £28. per ton; roll, £22. 10s. per ton; and rock, £17. 15s. per ton. Cream of tartar has been in very fair request, and is £11. 10s. to £11. 15s. per cwt. Tartaric acid has been rather more in demand, and is 3s. 2d. to 3s. 3d. per lb. Boracic acid has been more in request, and is £72. per ton for crystals and £74. per ton for powdered. Oxalic acid has been in fair demand, and is 1s. 2d. to 1s. 3d. per lb., according to time of delivery. Citric acid has been in quietly steady request, and is 4s. 4d. per lb. White acetate of lead has been in moderate inquiry, and is £83. to £85. per ton. Arsenic has been very quiet, and the price has been irregular. It may be given as £58. to £60. per ton for white powdered. Sulphate of copper has been in moderate demand. The price is: £40. to £41. per ton for use in the United Kingdom.

TYNE CHEMICAL REPORT.

TUESDAY.

The demand for chemicals continues active for both home and export, both caustic soda and bleaching powder being in strong request. Sulphur is very scarce and firm at £23. per ton. The following prices are per ton net: bleaching powder, softs and hards, £17. per ton net; caustic soda 74/77%, £23. 5s.; do., 70%, £22.; do., 60%, £20.; recovered sulphur, 2cwt. bags, £23.; hyposulphite of soda 5/7cwt. casks, £19.; do., 1cwt. kegs, £25.; sulphite of soda, 5/7cwt. casks, £12.; do., 1cwt. kegs, £20.; silicate of soda, 75° Tw., £9. 12s. 6d.; do., 100° Tw., £10.; do., 140° Tw., £10. 10s.; soda crystals, 2cwt. bags, £5. 10s.; sulphate of soda (salt-cake), in bulk, £4.; pure white sulphate of alumina, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18.; do., refined concentrated solid, 60-62%, £25.; hydrate of barium, crystals, £56.

COALS.—Market is very firm and it is almost impossible to satisfy demands. The general output throughout both Northumberland and Durham is stated to be on an increasing scale, but is still far below current needs. Nominally prices are as under: best Northumbrian steam, 95s. to 100s. per ton; second qualities, 90s. to 95s.; Northumberland small coals, 75s. to 80s., seconds, 70s. to 75s.; best Durham gas coals, 80s. to 85s., seconds, 70s. to 75s. 6d.; Durham bunker coals, 70s. to 80s., seconds, 60s. to 70s.; foundry coke, 95s. to 100s.; gas coke, 95s. to 100s., f.o.b. Tyne or Dunston.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Wednesday.

During the past week there has been a good amount of business passing among all classes of chemicals, and the tone of the market has been conspicuously brisk. Some big deals in different lines are reported, and, plus the numerous smaller transactions which are being put through, the market in this district may be said to be fairly active. There are no particular variations in prices worth recording, and the latest range of quotations may be said to be as follows. Arsenic, £56. per ton, net, Glasgow; bicarbonate of soda, £8. 15s. and £10. per ton, for 6-8 casks and 1cwt. kegs, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags, and borax crystals, £39. for 2cwt. bags, carriage paid; caustic soda, white, 70-72%, £24. per ton, net, Glasgow; chlorate of potash, 1s. 1d. per lb., net, Glasgow; chlorate of soda, £3. 4s. per cwt. net, Glasgow; citric acid, 4s. 4d. per lb. 5% Glasgow; cream of tartar 98% £11. 5s. per cwt., net, Glasgow; paraffin wax U.K. deliveries 125°, 6½d. to 6½d.; 121-30°, 5½d. to 5½d.; 118-20°, 5½d.; 110-120°, 4d. to 4½d.; and 98-102°, 4d. to 4½d.; salammuniac, £80. and £75. per ton, net, any port, for first and second lump respectively; salammuniac crystals, £85. per ton, net, Glasgow; saltpetre, £3. 4s. net, Glasgow; tartaric acid, 3s. 1d. per lb., 5% Glasgow.

Among the sea oils there is also good inquiry for anything available, and as far as whale oils are concerned purchasers have been having the opportunity of getting three varieties.

Brown and black have both retained their quotations of 76s. and 74s.; pale, however, has eased in value from 102s. to 97s., at which it is still selling; but, as has been the case for the past few weeks, yellow has been off the market. Newfoundland cod is in good inquiry at its old figure of 79s., and the same comment is applicable to both pale seal at 96s. and Menhaden at 86s.

There is nothing new reportable as far as the coal trade is concerned, and the old comment still holds good that all classes of fuel are in fairly strong demand. Inquiries from works continue to be fairly heavy, and there is not so much doing as far as the domestic side is concerned. From the export standpoint, business is quiet, and most of the available output continues to be monopolised for home purposes.

IMPORTS OF CHEMICAL PRODUCTS

AT THE PRINCIPAL PORTS OF THE UNITED KINGDOM.

BRISTOL.

Publication of Official Returns Suspended.

GLASGOW.

Week ending September 13.

BARIUM SULPHATE—
Antwerp, 20 t.

BARYTES—
New Orleans, 400 brls.

BORATE—
New Orleans, 5,279 sks.

CARBON BLACK—
New Orleans, 228 cs.

DYESTUFFS—
Tanning Extract
New York, 67 brls.

FISH OIL—
New York, 1,550 brls.

LITHOPONE—
Baltimore, 100 brls.

OCHRE—
Newport News, 518 brls.

dad, 1 c., £2.; Tientsin, 5 t. 19
c., £295.; Wellington, 4 t., £93.

DYESTUFFS (otherwise undescribed)

Petras, 4 c., £99.

FERRO MANGANESE—

New Orleans, 50 t.

GLUE, SIZE, AND GELATINE—

Durban, 2 pkgs.; Karachi, 20
pkgs.

LEAD CARBONATE—

Puerto Barrios, 3 c., £16.

MAGNESIA (CALCINED)—

Salvador, 1 c., £8.

MAGNESIUM CARBONATE—

Brisbane, 2 c., £14.

MAGNESIUM CHLORIDE—

Bombay, 9 t. 5 c., £159.; Ferrol,
10 t. 17 c., £177.

MAGNESIUM SULPHATE—

Addah, 5 c., £12.; Calcutta, 2 c.,
£3.; Christiania, 2 c., £4.;
Mantos, 1 c., £2.; Manas, 2 c.,
£2.; Monte Video, 5 c., £5.;
Puerto Barrios, 1 c., £1.

MAGNESITE—

Barcelona, 1 t. 13 c., £89.

MANGANESE PEROXIDE—

Syra, 1 t., £45.

MANGANESE SULPHATE—

New York, 5 t. 2 c., £260.

MURIATIC ACID—

Rotterdam, 19 c., £36.

NICKEL SULPHATE—

Antwerp, 40 t., £2,600.; Bar-
celona, 13 c., £41.; Bombay,
3 t. 10 c., £168.

OXALIC ACID—

Havre, 1 c., £10.; Hong Kong,
2 c., £14.

PHOSPHORIC ACID—

Brisbane, 1 c., £6.; Toronto,
10 c., £80.

PITCH—

Barcelona, 19 c., £32.; Sapele,
2 c., £1.

PITCH (STOCKHOLM)—

Acajutla, 10 c., £7.

POTASSIUM BICARBONATE—

Funchal, 1 c., £11.

POTASSIUM BICHRONATE—

Barcelona, 2 t., £317.; Dantzig,
5 t. 6 c., £842.; Havre, 4 c.,
£40.; Nantes, 1 t., £159.;
Smyrna, 1 t. 19 c., £312.

POTASSIUM CYANIDE—

Medellin, 3 c., £34.

POTASSIUM NITRATE—

Buenaventura, 1 c., £9.; Car-
tagena, 4 c., £19.

POTASSIUM PRUSSATE—

Barcelona, 7 c., £70.; Calcutta,
11 c., £20.

SALAMMONIAC—

Buenos Ayres, 2 t., £150.;
Monte Video, 9 c., £39.; Mon-
treuil, 1 t. 5 c., £90.; Rangoon,
3 t., £212.; Sydney, 5 c., £16.;
—Smyrna, 4 t. 1 c., £296.

Santos, 4 brls.; Shanghai, 297
pkgs.; Valencia, 1 pkg.; Vera
Cruz, 90 cks.

SODIUM SULPHATE—

Melbourne, 18 c., £38.

SULPHUR DIOXIDE—

Tientsin, 2 c., £8.

SULPHUR PRECIPITATE—

Corinto, 1 c., £8.

SULPHURIC ACID—

Monte Video, 16 c., £57.;
Tientsin, 1 t. 7 c., £36.

TALLOW—

Tripoli, 5 brls.

TANNIC ACID—

Christiania, 1 c., £15.

TARTARIC ACID—

Hong Kong, 2 c., £11.; Karachi,
10 c., £167.; La Guaira, 1 c.,
£18.; Puerto Barrios, 4 c., £55.

CHLORIDE OF TIN—

Lisbon, 2 c., £28.

TUNGSTIC ACID—

Rotterdam, 1 c., £50.

WOOD PRESERVATIVE—

Burutu, 1 c., £2.; Calicut, 1 c.,
£1.; Hsin Ho Wharf, 1 c., £2.;
Lome, 6 c., £10.; Oron, 3 c., £5.

ZINC SULPHATE—

Batavia, 10 t. 3 c., £270.;
Buenos Ayres, 1 c., £10.

LONDON.

Week ending September 10.

ACETIC ACID—

Alexandria, 33 cks., £451.; Ant-
werp (F.), 6 cks., £75.; Banga-
lore, 9 cs., £38.; Genoa (F.), 29
brls., £370.; Timaru, 12 cs.,
£36.

ACETO SALICYLIC ACID—

Beyrout, 11 cs. (pt.), £6.;
Constantinople, 2 cs., £72.;
Fiume, 3 cs. (pt.), £56.; Sydney,
2 cs., £42.

ACETONE—

Brussels, 1 dr., £28.; Antwerp,
14 drms., £498.

ALUM—

Brussels, 10 cs., £7.

ALUM (CHROME)—

Brussels, 2 t. 5 c., £217.

ALUMINA HYDRATE—

Genoa, 28 cks., £520

AMMONIA—

Alexandria, 27 pkgs., £62.;
Bombay, 24 cs., £153.; Cap-
town, 34 cs., £67.; Channel
Islands, 12 cs., £23.; Colombo,

3 c., £12.; Lourenco Marques,
4 c., £12.; Naples, 4 cks., £64.;
Perth, 15 cks., £49.; Melbourne,
8 c., £33.

AMMONIUM PERCHLORATE—

Antwerp, 167 bxs., £209.

AMMONIUM PHOSPHATE—

Algiers (F.), 3 t. 18 c., £432.;
Italy, 6 c., £38.

AMMONIUM SULPHATE—

Durban, 242 t., £6,050.

AMMONIUM SULPHOCYANIDE—

Osaka, 1 ck., £18.

AMYL ACETATE—

Brussels, 1 dr., £84.; Alex-
andria, 1, 3 (pt.), £25.; Calcutta,
2 cs., £18.; Sydney, 2 cs., £16.

AMYL SALICYLATE—

Fiume, 1 cs. (pt.), £7.

ANTIMONY—

Lisbon, 5 t.

ANTIMONY REGULUS—

Rotterdam, 40 t. 17 c.

ANTIMONY SULPHIDE—

Antwerp, 16 pkgs., £458.; Bahia,
6 kgs., £36.; Bilbao, 3 cks., £60.;
Boston, 15 brls., £113.; Gothen-
burg, 10 cks., £170.; Rotterdam,
2 cks., £266.; Stockholm, 7 cks.,
£150.

ANTIMONY TARTRATE—

Copenhagen, 4 kgs., £73.

ARSENIC—

Pt. Elizabeth, 1 t., £38.; Pt.
Elizabeth (F.), 1 t., £69.;
Rouen, 10 t. 2 c., £600.

BARBITONE—

Sydney (F.), 5 cs. (pt.), £19.

BARIUM HYPOPHOSPHITE—

New York, 2 cs., £68.

BARIUM CHLORIDE—

Barcelona, 11 cks., £84.

BEES WAX—

Batoum, 4 c.

BENZOIC ACID—

Calcutta, 1 ck., £134.; Fiume,
2 cs. (pt.), £37.

BENZYL ACETATE—

Fiume, 1 cs. (pt.), £10.

BENZYL CHLORIDE—

Rotterdam, 1 ck., £11.

BISMUTH BICHLORIDE—

Calcutta, 1 ck. (pt.), £9.

BISMUTH CARBONATE—

Rotterdam, 1 cs. (pt.), £9.;
Stockholm, 1 cs. (pt.), £43.

BISMUTH CITRATE—

Pt. Elizabeth, 1 cs. (pt.), £5.

BISMUTH OXYDOGALLATE—

Rotterdam, 1 cs. (pt.), £19.

BISMUTH SALICYLATE—

Gothenburg, 2 cs., £154.; Pt.
Elizabeth, 1 cs. (pt.), £10.

BISMUTH SUBGALLATE—

Constantinople, 1 cs. (pt.), £42.;
Gothenburg, 1 cs. (pt.), £85.;
Rotterdam, 1 cs. (pt.), £84.;
Stockholm, 1 cs. (pt.), £42.

BISMUTH SUBNITRATE—

Calcutta, 1 ck. (pt.), £10.; Ant-
werp, 3 cs., £395.; Constanti-
nople, 1 cs., £156.; Copenhagen,
1 cs., £152.

BISMUTH SUBNITRATE—

Gottfenburg, 1 cs. (pt.), £76.; Rotterdam, 1 cs., £76.; Stockholm, 1 cs. (pt.), £76.

BISMUTH SUBSALICYLATE—

Copenhagen, 2 cs., £145.; Rotterdam, 1 cs. (pt.), £46.

BLEACHING POWDER—

Alexandria, 1 c., £12.

BORAX—

Alexandria, 10 c., £12.; Antwerp, 4 t. 16 c., £255.; Antwerp, Switzerland, *via*, 1 t., £46.; Copenhagen, 1 t., £40.; Durban, 3 c., £7.; East London, 5 c., £11.; Gibraltar, 10 c., £20.; Mauritius, 2 c., £5.; Rotterdam, 5 t. 4 c., £259.

Melbourne, 2 cs. (pt.), £37.

COPPER SUBOXIDE—

Bergen, 3 cks., £156.; Copenhagen, 5 drms., £44.

COPPER SULPHATE—

Brussels, 2 c., £6.; Mollendo, 10 c., £28.; Salonica, 1 t., £40.

COPPER SULPHOCYANIDE—

Copenhagen, 15 drms., £113.

COPPERAS—

Delagoa Bay, 10 cs., £5.

CREAM OF TARTAR—

Bahia, 2 c., £12.; Bombay (F.), 1 c., £13.; Calcutta (F.), 2 c., £28.; Copenhagen, 4 t. 2 c., £940.; Delagoa Bay, 4 c., £61.; Durban, 5 c., £82.; Horsens, 18 c., £96.; Jaffa, 1 c., £9.; Madras, 2 c., £60.; Rio de Janeiro, 1 ck., £13.; Wellington (F.), 5 t., £1,038.

DISINFECTANTS (otherwise undes.)

Alexandria, 17 c., £66.; Antwerp, 4 t., £530.; Ascension, 12 c., £18.; Bangkok, 3 t. 3 c., £126.; Bombay, 1 c., £5.; Bergen (F.), 11 c., £70.; Belawan, 5 c., £5.; Buenos Ayres, 32 t. 9 c., £1,422.; Cape Town, 4 t. 7 c., £182.; Colombo, 1 c., £7.; Copenhagen, 4 c., £30.; Durban, 9 c., £40.; Gibraltar, 2 c., £5.; Gisborne, 4 c., £14.; Hong Kong, 1 c., £8.; Jamaica, 5 c., £15.; Madras, 1 t. 11 c., £33.; Malta, 7 c., £13.; Montreal, 2 c., £7.; Paris, 4 t. 13 c., £120.; Pernambuco, 1 t. 5 c., £150.; Port Said, 3 c., £12.; Pt. Swettenham, 15 c., £36.; Rosario, 5 c., £122.; Sandakan, 7 c., £16.; Sarawak, 1 t., £38.; Shanghai, 14 t. 6 c., £720.; Singapore, 2 t. 15 c., £125.; Sydney, 10 c., £28.; Trinidad, 3 t. 14 c., £133.; Trondhjem (F.), 11 c., £70.

ETHER ACETIC—

Canton, 1 cs., £10.

ETHER (SULPHURIC)—

Canton, 1 cs., £15.

FISH OIL—

Marseilles, 4 t. 3 c.; Nantes, 1 t. 14 c.

FLUORIC ACID—

Cape Town, 2 cs., £31.; Pt. Elizabeth, 3 cs., £56.; Sydney, 2 cs., £24.

FORMIC ACID—

Sydney (F.), 18 cs., £113.

FULLER'S EARTH—

Los Angeles, 50 t.; Marseilles, 100 t.; San Francisco, 50 t.; Tacoma, 50 t.; Vancouver, 20 t.

GALLIC ACID—

Madras, 1 cs. (pt.), £23.; Melbourne, 1 cs., £41.

GELATINE—

Rangoon, 1 c.

GLUE—

Pt. Swettenham, 3 c.

GLUE, SIZE, AND GELATINE—

Alexandria, 2 t. 2 c.; Adelaide, 2 c.; Antwerp, 7 t. 4 c.; Batoum, 15 c.; Bilbao, 6 t.; Boulogne, 1 t. 13 c.; Buenos Ayres, 3 c.; Calcutta, 1 t. 10 c.; Christchurch, 2 t. 2 c.; Colombo, 14 c.; Copenhagen, 2 t. 1 c.; Dunedin, 1 t. 5 c.; Durban, 1 c.; East London, 1 c.; Gibraltar, 10 c.; Karachi, 2 t. 5 c.; Kobe, 2 t.; Melbourne, 4 c.; Rotterdam, 11 c.; Sydney, 2 t.; Yokohama, 2 t. 10 c.

GLYCERINE—

Calcutta, 2 c., £14.; Canton, 1 c., £7.; Madras, 2 c., £14.; Piraeus, 2 c., £15.; Pt. Elizabeth, 1 c., £10.; Rouen, 1 t., £140.; Shanghai, 10 c., £55.; Swatow, 1 c., £8.

HEXAMETHYLENETETRAMINE

Athens (F.), 1 cs. (pt.), £18.

HYDROCYANIC ACID—

Aden, 1 c., £7.; Lourenco Marques, 2 c., £5.; Rio de Janeiro, 1 c., £5.

HYDROFLUORIC ACID—

Tokio, 5 cs., £17.

HYDROGEN PERCHLORIDE—

Rosario, 1 cs., £36.

HYDROGEN PEROXIDE—

Bergen, 14 cs., £60.; Durban, 2 cs., £6.

HYPOPHOSPHITE SALTS—

Montreal, 8 c., £231.

IODINE (RESUBLIMED)—

Copenhagen, 1 cs., £90.; Gothenburg, 2 cs., £202.; Rotterdam, 1 cs., £90.

IRON AND AMMONIUM CITRATE

Ghent, 2 cs., £63.; Rotterdam, 1 cs. (pt.), £16.

LACTIC ACID—

Calcutta, 1 ck. (pt.), £10.; Constantinople, 1 ck., £34.; Melbourne (F.), 5 cs., £90.

LEAD ACETATE—

Calcutta, 10 cks., £42.; Antwerp, 35 cks., £675.

LEAD ARSENATE—

Bordeaux, 20 drms., £112.

LEAD LINOLEATE—

Copenhagen, 2 brls., £53.

LEAD OXIDE—

Salonica, 1 ck., £21.

LITHIUM BENZOATE—

Athens, 1 cs. (pt.), £8.

MAGNESIA (CALCINED)—

Alexandria, 1 cs., £26.; Halmstead, 5 cks., £47.; Marmagao, 2 cs., £7.; Pernambuco, 1 cs., £14.

MAGNESIUM OXIDE—

Brussels, 4 cs., £38.; Halmstead, 5 cks., £23.

MAGNESIUM SULPHATE—

Aden, 4 c., £7.; Bombay, 2 c., £6.; Brussels, 3 c., £5.; Canton, 6 c., £10.; Cyprus, 3 c., £6.; Karachi, 8 c., £20.; Marmagao, 2 c., £6.; Pt. Elizabeth, 1 t., £45.; Porto Alegre, 1 t. 2 c., £52.; Rio Grande do Sol, 1 t., £52.; Singapore, 2 t., £70.;

MAGNESIUM SULPHATE—

Wellington, 1 t., £38.

MANGANESE BORATE—

Antwerp, 3 cks., £38.

MANGANESE HYPOPHOSPHITE—

Gothenburg, 1 cs. (pt.), £5.

MANGANESE LINOLEATE—

Copenhagen, 1 brl., £18.

MANGANESE PEROXIDE—

Naples, 2 cks., £75.

MANGANESE RESINATE—

Melbourne, 2 cs. (pt.), £7.

MERCURY BICHLORIDE—

Copenhagen, 1 cs., £70.

MERCURY CHLORATE—

Gothenburg, 1 cs. (pt.), £20.

MERCURY CHLORIDE—

Durban, 1 cs. (pt.), £9.

MERCURY PRECIPITATE—

Gothenburg, 1 cs. (pt.), £43.

MERCURY SALTS—

Gothenburg, 1 cs. (pt.), £37.

MERCURY SULPHOCYANIDE—

Bombay, 1 cs., £11.

METHYL SALICYLATE—

Fiume, 2 cs. (pt.), £11.

NAPHTHALENE SALICYLATE—

Buenos Ayres (F.), 2 cs. (pt.), £16.

NICKEL & AMMONIUM SULPHATE—

Canton, 2 cs., £20.

NICKEL OXIDE—

Antwerp, 1 ck., £11.

NICKEL SALTS—

Antwerp, 3 cs., £16.

NICKEL SULPHATE—

Brussels, 15 cs., £194.

NITRIC ACID—

Rio de Janeiro, 1 c., £8.

OXALIC ACID—

Athens, 9 pkgs. (pt.), £42.

PARAFFIN WAX—

Bergen, 2 c.; Bordeaux, 1 t.; Calais, 5 t.; Libau, 4 t.; Valencia, £300.

PEARL ASH—

Cape Town, 2 pkgs., £17.

PHOSPHATE OF LIME—

Paris, 3 cks., £15.

PHOSPHORIC ACID—

Auckland, 4 cs., £30.; Sydney, 89 cs., £374.; Toronto, 84 cbs., £570.

PHOSPHORUS (AMORPHOUS)—

Bombay, 1 cs., £14.

PHOSPHORUS SESQUISULPHIDE

Barcelona, 30 cs., £170.; Santander, 20 cs., £313.; Valencia, 60 cs., £879.

PITCH—

Ferrol, 1 t.

PLUMBAGO—

Boulogne, 4 c.; Ghent, 4 t., 11 c.

POTASSIUM ACETATE—

Freetown, 2 cs., £14.; Sydney, 4 cs., £60.

POTASSIUM BICARBONATE—

Bangkok, 1 kg., £11.

POTASSIUM BICROMATE—

Cologne, 53 brls., £2,950.; Paris, 1 ck., £60.

POTASSIUM BINOXALATE—

Santander, 6 kgs., £62.

POTASSIUM BROMIDE—

Buenos Ayres (F.), 2 cs. (pt.), £8.

POTASSIUM CARBONATE—

Athens, 1 ck., £25.

POTASSIUM CITRATE—

Colombo, 1 cs., £17.; Gothenburg, 1 cs. (pt.), £8.

POTASSIUM CYANIDE—

Brussels, 2 c., £29.; Buenos Ayres, 1 cs., £18.; Foochow, 1 cs. (pt.), £7.

POTASSIUM HYPOPHOSPHITE—

POTASSIUM IODIDE—

Antwerp, 1 cs., £39.; Bahia Blanca, 1 cs. (pt.), £38.; Buenos Ayres (F.), 2 cs. (pt.), £19.; Gothenburg, 3 cs., £420.; Copenhagen, 1 cs., £75.; Rotterdam, 1 cs., £76.

POTASSIUM METABISULPHITE—
Athens, 1 ck., £22.; Paris, 4 cs., 4 cks., £398.; Sydney, 2 cs., £26.

POTASSIUM PERMANGANATE—
Athens (F.), 1 cs., £10.

POTASSIUM PRUSSATE—
Brussels, 1 ck., £16.; Buenos Ayres, 1 cs., £35.; Ghent, 1 cs., £35.

POTASSIUM SULPHOGUAIACOLATE—
Athens (F.), 1 cs. (pt.), £48.; Osaka (F.), 4 cs., £347.

PRUSSIAN BLUE—
Genoa, 4 cks., £146.

PYROGALLIC ACID—
Melbourne (F.), 1 cs., £62.

QUININE—
Calcutta, 2,303 ozs.; Italy, 9,216 ozs.; Penang, 776 ozs.

SALACETOS—
Paris, 20 brls., £375.

SALICYLIC ACID—
Auckland, 3 kgs., £35.; Aalborg, 1 bx., £6.; Constantinople, 2 cs., £28.; Fiume, 2 cs. (pt.), £35.; Singapore, 3 cs., £30.

SALT—
Aden, 3 c.; Cape Town, 4 c.; Cyprus, 10 c.; Singapore, 8 c.

SALTPETRE—
Barcelona, 5 t., £260.; Delagoa Bay, 3 c., £9.; Durban, 2 t. 2 c., £143.; East London, 9 c., £26.; Lisbon, 2 t. 19 c., £146.; Mombasa, 5 c., £17.; New York, 150 t., £5,787.; Pernambuco, 5 t. 6 c., £423.; Pt. Elizabeth, 1 t. 4 c., £80.; Santos, 14 t. 14 c., £920.; Singapore, 1 c., £5.; Valencia, 2 t. 1 c., £108.

SHEEP DIP—
Buenos Ayres, 42 t. 14 c., £2,300.; Dunedin, 1 t. 7 c., £75.; Durban, 6 t. 9 c., £297.

SILVER NITRATE—
Rotterdam, 1 cs. (pt.), £55.

SOAP—
Alexandretta, 3 c.; Alexandria, 2 t. 1 c.; Antwerp, 167 t. 19 c.; Amsterdam, 1 t. 8 c.; Auckland, 1 t. 13 c.; Bahia, 3 c.; Bangkok, 1 t.; Barbados, 23 t. 11 c.; Beira, 2 c.; Bilbao, 7 c.; Bombay, 3 t. 13 c.; Brisbane, 2 c.; Boulogne, 53 t.; Buenos Ayres, 1 t. 2 c.; Callao, 3 c.; Calais, 2 t. 8 c.; Calcutta, 4 t. 15 c.; Cartagena, 2 c.; Channel Islands, 3 t. 3 c.; Colombo, 1 t. 16 c.; Constantinople, 7 c.; Copenhagen, 5 t. 11 c.; Delagoa Bay, 1 c.; Demerara, 15 t. 14 c.; Djibouti, 2 c.; Durban, 1 t. 3 c.; Dunedin, 2 c.; East London, 2 c.; Freetown, 1 c.; Genoa, 5 c.; Gothenburg, 12 t. 6 c.; Guayaquil, 1 c.; Halifax, 4 c.; Hong Kong, 1 t. 1 c.; Havre, 41 t. 5 c.; Italy, 3 c.; Jaffa, 9 c.; Gibuti, 1 c.; Karachi, 2 t. 12 c.; Kilindini, 4 c.; Kobe, 4 c.; Liban, 9 t. 15 c.; Lisbon, 1 c.; Lytleton, 3 c.; Madras, 3 c.; Loanda, 5 c.; Mauritius, 6 c.; Monte Video, 2 t. 1 c.; Messina, 1 t. 5 c.; Montreal, 10 c.; Melbourne, 4 c.; New Plymouth, 14 c.; New York, 1 t. 9 c.; Ostend, 11 c.; Orebri, 1 t. 5 c.; Paramaribo, 1 t. 2 c.; Paris, 1 t. 11 c.; Perth, 2 c.; Piraeus, 5 c.; Pt. Said, 16 c.; Punta Arenas, 1 c.; Raigoon, 3 c.; Rio de Janeiro, 8 c.; Rotterdam, 73 t. 5 c.; Santander, 1 c.; Santos, 2 c.; Seville, 5 c.; Shanghai, 5 c.; Singapore, 4 c.; Smyrna, 3 c.; Sourabaya, 3 c.; Talcahuano, 2 c.; Toronto, 2 c.; Treport, 9 c.; Trinidad, 15 t. 14 c.; Wellington, 7 c.

SODA—
Rosario, 2 t. 9 c., £25.

SODA ASH—
Genoa, 10 t., £100.; Liban, 30 t., £200.; Pernambuco, 10 c., £8.

SODIUM AND POTASSIUM TARTRATE—
Athens, 1 cs. (pt.), £11.

SODIUM ARSENITE—
Durban, 2 t. 1 c., £110.

SODIUM BICARBONATE—
Bangkok, 5 c., £30.; Calcutta, 5 c., £16.; Canton, 10 c., £15.; Cape Town, 3 c., £6.; Constantinople, 6 c., £31.; Hong Kong, 10 c., £13.; Lourenco Marques, 5 c., £10.; Montreal, 7 c., £15.; Santos, 5 c., £5.; Shanghai, 13 c., £20.; Smyrna, 5 c., £22.

SODIUM BISULPHATE—
Rouen, 15 c., £24.

SODIUM BISULPHITE—
Bangkok, 6 c., £8.; Antwerp, 5 t. 10 c., £139.; Rouen, 6 t. 17 c., £216.

SODIUM CARBONATE—
Brussels, 11 c., £12.; Kobe, 5 c., £13.

SODIUM CITRATE—
Gothenburg, 1 cs. (pt.), £26.

SODIUM HYDROSULPHITE—
Genoa, 1 t. 2 c., £364.

SODIUM HYPOPHOSPHITE—
Gothenburg, 1 cs. (pt.), £13.

SODIUM GLYCEROPHOSPHATE—
Copenhagen, 1 cs., £78.

SODIUM IODIDE—
Gothenburg, 1 cs., £90.; Rotterdam, 1 cs., £103.

SODIUM HYPOSULPHITE—
Antwerp, 2 t. 10 c., £53.; Busrah, 4 c., £8.

SODIUM METABISULPHITE—
Algiers, 6 t. 4 c., £176.

SODIUM PHOSPHATE—
Odense, 1 t., £50.

SODIUM PRUSSATE—
New York, 30 t., £1,890.

SODIUM SALICYLATE—
Calcutta, 2 cs., £14.; Colombo, 1 cs., £11.; Fiume, 1 cs. (pt.), £11.; Constantinople, 2 cs., £10.

SODIUM SILICATE—
Durban, 5 c., £13.

SODIUM SULPHIDE—
Brussels, 1 cs., £5.; Sydney, 3 cs. (pt.), £7.

SODIUM SULPHITE—
Adelaide, 2 c., £8.; Bergen, 10 t. 2 c., £158.; Brussels, 6 c., £8.; Bushire, 1 t. 12 c., £161.; Pt. Swettenham, 1 t., £35.

STRONTIUM NITRATE—
Bombay, 62 pkgs., £376.; Naples, 4 cks., £90.

SULPHATE OF QUININE—
Buenos Ayres, 540 ozs.; Calcutta, 8,000 ozs.

SULPHUR—
Brussels (F.), 1 t., £31.; Pernambuco, 6 t. 17 c., £170.

SULPHUR (ROLL)—
Paris, 5 t., £120.

SULPHUR PRECIPITATE—
Halmstead, 10 c., £39.

SULPHURIC ACID—
Alexandria, 7 t., £178.; Athens, 1 t., £25.; Beira, 2 t. 10 c., £88.; Channel Islands, 1 t. 13 c., £20.; Pt. Sudan, 3 t. 10 c., £140.; Rio de Janeiro, 4 c., £20.; Sierra Leone, 3 c., £15.; Smyrna, 2 c., £18.

SUPERPHOSPHATES (otherwise undescribed)—
Italy, 1 t.

TALLOW—
Antwerp, 8 c.; Paris, 30 c.

TANNIC ACID—
Amsterdam, 1 ck., £19.

TARTARIC ACID—

Aden (F.), 1 cs., £6.; Bombay (F.), 2 c., £29.; Calcutta (F.), 1 cs., £10.; Cape Town (F.), 3 c., £52.; Copenhagen, 10 c., £182.; Copenhagen (F.), 4 c., £79.; Delagoa Bay (F.), 4 c., £85.; Durban, 1 c., £27.; East London (F.), 1 c., £21.; Karachi (F.), 1 c., £11.; New York (F.), 6 t. 15 c., £2,330.; Pt. Elizabeth, 2 c., £48.; Pt. Elizabeth (F.), 2 c., £47.; Raigoon (F.), 2 c., £35.; Singapore, 5 c., £95.

TARTRATE—
Pt. Elizabeth, 10 kgs., £61.

TERPINE HYDRATE—
Stockholm, 2 kgs., £45.

TRIPHENYL PHOSPHATE—
Boston, 12 cs., £517.

VEGETABLE PITCH—
Calais, £64.

VEGETABLE WAX—
Rotterdam, 1 t.

WAX—
Genoa, 3 c.; Treport, 2 t.

WHITE ACID—
Sydney, 1 cs., £35.

WHITE LEAD—
Cochin, £12.; Naples, £250.; Oran, £60.; Paris, £1,136.; Pt. Elizabeth, £109.; Timaru, £58.

ZINC PERCHLORIDE—
Constantinople, 1 ck., £65.

ZINC SULPHIDE—
Halmstead, 1 ck., £11.; Melbourne, 1 ck., £6.

MANCHESTER

Week ending September 10.

ALUMINA SULPHATE—
Antwerp, 33 bgs.; Montreal, 25 bgs.

AMMONIUM MURIATE—
Montreal, 6 cs.

BLEACHING POWDER—
Montreal, 100 cs.

CAUSTIC SODA—
Montreal, 250 cs.

COAL PRODUCTS (otherwise undescribed)—
Antwerp, £58.; Bombay, £770.; Philadelphia, £280.

DEXTRENE—
Antwerp, 10 bgs.

DYE STUFFS—
Aniline Colours
Treport, 1 kg.

FERRIC MANGANESE—
Boston, 50 t.; Philadelphia, 1,000 t.

POTASSIUM PRUSSATE—
Montreal, 5 cks.

SALAMMONIAC—
Montreal, 10 cks.

SALT—
Montreal, 7,500 sks.; Quebec, 2,400 sks., 2,400 pkgs.; St. John, 50 t., 10,122 sks.

SOAP—
Antwerp, 50 pkgs., 411 cs.; Montreal, 24 cks.

SODA ASH—
St. Johns, 228 pkgs.

SODIUM CARBONATE—
St. Johns, 375 pkgs.

SODIUM PHOSPHATE—
Dunkirk, 230 bgs.

MIDDLESBROUGH.

Week ending September 13.

AMMONIUM SULPHATE—
Kobe, 1,937 t. 7 c., £37,616.; Yokohama, 1,746 t. 15 c., £33,694.

BARIUM SULPHIDE—
Karachi, 1 t., £23.

CAUSTIC SODA—
Calcutta, 60 t. 7 c., £1,207.

CHEMICALS (otherwise undescribed)
Calcutta, 42 t. 8 c., £615.; Singapore, 17 t. 15 c., £286.

COAL PRODUCTS—

Creosote Salts—
Cape Town, 6 c., £12.

Disinfectants—

Algoa Bay, 8 c., £15.; Cape Town, 10 t. 3 c., £333.; Calcutta, 4,784 galls., £587.; East London, 8 c., £15.; Natal, 10 t. 3 c., £333.

Naphthalene—

Algoa Bay, 1 t., £17.; East London, 1 t. 10 c., £26.; Tientsin, 15 t., £240.

Pitch—

Antwerp, 476 t. 8 c., £1,651.

DISINFECTANTS—

Algoa Bay, 6 c., £12.; Cape Town, 10 c., £22.; East London, 6 c., £12.; Natal, 6 c., £12.

MAGNESIA (CALCINED)—

Rouen, 1 t. 9 c., £177.

SALT—

Cape Town, 16 c., £34.; Delagoa Bay, 1 t. 1 c., £48.; East London, 2 t. 8 c., £102.; Shanghai, 6 c., £14.

SODIUM SILICATE—

Calcutta, 9 t. 17 c., £120.

NEWCASTLE-ON-TYNE

Week ending September 13.

ALUMINA SULPHATE—

Rotterdam, 10 t.

ANTIMONY—

Antwerp, 22 t.; Gothenburg, 15 t.; Rotterdam, 125 t. 10 c.

BARIUM CARBONATE—

Dunkirk, 6 t.

BLEACHING POWDER—

Gothenburg, 25 t.; Rotterdam, 4 t. 19 c.

CAUSTIC SODA—

Gothenburg, 40 t.; Narvik, 10 t.

COPPER OXIDE—

Bergen, 5 t. 5 c.; Copenhagen, 12 c.

PITCH—

Dunkirk, 7 t.

RED LEAD—

Bergen, 2 t. 1 c.; Helsingfors, 10 t.; Narvik, 1 t.; Rotterdam, 5 t. 17 c.

SOAP—

Copenhagen, 4 t. 15 c.

SODA CRYSTALS—

Rotterdam, 40 t.

SODIUM SULPHIDE—

Antwerp, 4 t. 5 c.

SODIUM SULPHITE—

Gothenburg, 19 c.

SULPHUR—

Gothenburg, 15 t.

SULPHUR (ROCK)—

Rotterdam, 10 t.

WHITE LEAD—

Antwerp, 17 t. 8 c.; Gothenburg, 5 t.

N. & S. SHIELDS.

Week ending September 13.

NIL.

STOCKTON-ON-TEES.

Week ending September 13.

NIL.

SWANSEA.

Week ending September 13.

COPPER SULPHATE—

Antwerp, 5 c., £12.; Santander, 15 t., £750.

NICKEL SALTS—

Santander, 1 t. 4 c., £25.

NICKEL SULPHATE—

Antwerp, 6 t. 8 c., £355.; Barcelona, 2 t. 19 c., £250.; Rotterdam, 9 t., £2,000.

PRICES CURRENT.

THURSDAY, Sept. 18, 1912.

PREPARED BY MESSRS. HIGGINBOTTOM AND CO., 21, SPRING GARDENS, MANCHESTER.

The values stated are F.O.R. at makers' works, or at usual ports of shipment in U.K., unless otherwise specified
The prices in different localities may vary

Acids:—

		£	s.	d.

ORGANISING SCIENTIFIC RESEARCH.

LITTLE is known of the attempt to form a Scientific Research Association, and still less, probably, that the attempt came to a premature end at the British Association meeting at Bournemouth. This event in the scientific world has arisen because certain scientific people felt very strongly that industrial research was being concentrated upon too much by the Department of Scientific and Industrial Research, and that scientific research *per se* was in danger of being swamped in the process; but they were unable to convince any considerable number of their brother scientists that their method of dealing with the question was the right one. The aim of the projected Scientific Research Association was to organise scientific research and to formulate a scheme for the State endowment of such research. The criticism immediately met with when the suggestion to form this new association was made was: Why establish a new organisation—Why should not some existing society do it—the Royal Society, the British Association, or the British Science Guild? The answer of the promoters was that the Royal Society would not do it, and, indeed, its constitution was quite unsuitable, because although it received a grant of £5,000. for research, it merely distributed the money after inquiry as to whether they were justified by the particular research proposed. Moreover, the association of younger men who have not become Fellows is an important feature of any scheme that aims at being really representative. The British Association might do, if it would consent to reorganise its constitution and permanent staff for the purpose—perhaps a good deal to ask,—whilst the British Science Guild was understood to regard any such detailed organisation of research as not within its sphere, though it looked upon the proposal to create such an organisation with sympathy and approval. Having answered their own questions in this way, those concerned proceeded to take the necessary preliminary steps to bring the Scientific Research Association into being. In the spring of this year a provisional committee was appointed, and a circular was sent to about 2,000 people who were thought likely to give their support. Although between 150 and 200 supporters were found, there were some eminent people who held that the work of the proposed new organisation ought to be done by existing bodies. Consequently, it became evident that the estimated sum necessary to pay expenses did not seem likely to be forthcoming, and the promoters were at something approaching a deadlock. It was in these circumstances that advantage was taken of so large a number of scientists being in Bournemouth in connection with the British Association

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers)	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and no issue between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Telephone Numbers are:—

London: 13692, Central. Manchester: 3080, Central.

Manchester Address is Barten House, 66, Deansgate.

to hold a meeting to discuss the position, although it must be understood that the meeting was not in any way convened by the British Association. That meeting, it must be confessed, was quite unrepresentative, and it was clear from the lack of practical support which was forthcoming that there was nothing to do but abandon the idea, which, by the way, had its origin in Cambridge, and the provisional committee which was appointed to carry out the preliminary work consisted entirely of members of that University, though with powers of co-option. The position is that there is a general agreement that scientific research needs to be looked after and co-ordinated by some organisation, but doubt exists as to whether it is necessary to bring a new organisation into existence for the purpose.

AN INDICTMENT OF THE FUEL BOARD.

RECENT events in the domain of scientific research, as distinct from industrial research, tend to suggest that the cry for preventing the overlapping of scientific research is not so sound as it seemed at first. Professor Gray, in his presidential address to Section A of the British Association, complained that the authorities who have taken over the supervision of scientific research are adopting a policy of too much concentration; and at the same meeting of the British Association—and since then at the meeting of the Iron and Steel Institute in London—we have had a valuable object lesson in the policy of the Fuel Research Board of the folly of the concentration of scientific research. Professor Bone, Professor Armstrong, and others, as stated in these columns last week, have made a strong indictment against Sir George Bellby, the Chairman of the Board, that the policy of concentration is being carried to unwarranted limits, and it has, indeed, developed into a secrecy, the rigour of which was not excelled in regard to the most cherished of our secrets during war time. In industrial research all concerned in the particular industry are brought together for the common good, and all the brains in the industry are pooled for that purpose. The very antithesis appears to hold as far as the particular branch of scientific research covered by the Fuel Research Board is concerned. In the very commencement it has turned aside and flouted those scientists who were responsible for bringing it into existence, and pointing the line of investigation which the needs of our industries demanded. We agree with the view that overlapping in scientific research should not be discouraged, and in the circumstances which surround the actions of the Fuel Research Board it should positively be encouraged. So concentrated have the efforts of the Board become, and so jealous is it that nobody else shall do anything, that if Professor Bone, for instance, has a promising student whom he wants to put on to a special research, and asks the Department of Scientific and Industrial Research for a grant, he is told that he cannot have one, because the particular research comes within the scope of the Fuel Board. It will never do to leave ourselves dependent upon such a state of affairs. It is extremely unfortunate that in consequence of the establishment of the Fuel Research Board nothing has been done during the past two or more years by private interest in this matter, which was admittedly vitally urgent in 1915. Knowing

the activity and earnestness, to say nothing of the ability, of those who started the crusade for fuel economy in 1915, we are not surprised that the British Association Fuel Economy Committee has been re-established. Moreover, the Federation of British Industries has formed a committee to do many of the things which the Fuel Research Board was intended to carry out, and some which it was not, whilst the Iron and Steel Institute has quickly collected a fund of over £10,000 to deal with research into fuel economy as it affects those industries. Sir George Bellby is determined not to enter into any controversy, but, whether the critics be right or wrong—there may be a sufficient answer to them—we hardly think that he can maintain silence much longer, even if it mean anticipating somewhat the promised report concerning the accomplished and future work of the Board. Moreover, a statement is due as to why so many acknowledged experts—men who brought the whole question into prominence—are cold-shouldered.

NITRATE OF SODA.

As recently stated in these columns the Producers' Association had threatened to reduce its selling prices, if necessary, to 8s. and 8s. 2d. respectively for ordinary and refined nitrate, in the event of the non-associated companies continuing to stand out. There has been no occasion to carry out this threat—described by us as *brutum fulmen*—for the Association has sold at 9s. per quintal f.o.b. (presumably for ordinary quality) 500,000 tons for delivery October, 1919, to March, 1920. The "climbing down" from the "fixed price" of 10s. 1d. (10s. 4d. for refined) has been voluntary, and the transaction may be considered highly satisfactory from the sellers' point of view, considering that 30,000 to 40,000 tons in second hands fetched only 8s. 8d. to 8s. 9d. per quintal two months ago. It would be interesting to know the buyers in the above important deal, representing, with freight, insurance, and charges, over £15,000,000. sterling. But the only semi-official information is the somewhat obvious one that "a large portion will probably find its way direct to Continental consuming markets." We may point out in this connection that the producers outside the Association have already entered into a three-years' contract for the consignment of 300,000 tons per annum to Belgium, the signatories being the Chilean Chargé d'Affaires in Brussels and the firm of Corblet et Cie. Germany and Austria formerly the chief importers of the Chilean fertiliser, and for the present out of the business, while 650,000 tons was the maximum yearly quantity taken by the rest of the Continent (including Egypt) before the war, when nitrate cost less than half the present figure. It is difficult to see where several hundred steamers and sailing vessels can be found to load nitrate in Chile within the next six months; but the financial and lay Press, enthusiastically hailing the termination of the deadlock, foreshadows the early disposal of a further quantity of 500,000 to 750,000 tons by the Producers' Association. The consequence is a "boomlet" in nitrate shares; but, as stated in our last issue, the stocks in Chile on the 1st inst. were 1,652,540 tons, and gratifying as is a commencement of "mobilisation" of these, we take leave to doubt the advent of the nitrate millennium. The acid test will be applied by the consumer next spring.

SOME MICROSCOPICAL FEATURES OF WHITE LEAD.

By JAMES SCOTT.

ALTHOUGH white lead is regarded as lead carbonate, it has been satisfactorily proved that if it should happen to be absolutely pure in this respect it will be inferior in use to the commoner so-called impure varieties. To be effective in action, condition, and durability, it must consist of 70 to 75 per cent. of lead carbonate, and 30 to 25 per cent. of lead hydrate. If the amount of hydrate is in excess of the higher figure the desirable opacity of the pigment is seriously diminished; while, on the other hand, if less hydrate than the lower figure is present, there is a loss of binding power and general lack of efficiency.

Most of the commercial productions come fairly well within this category; but exceptions have frequently been met with. If the quantity of hydrate goes very much above, or below, either of the extremes noted, the white lead will become absolutely useless as a permanent substance. Consequently, although it is customarily referred to as $PbCO_3$, white lead is more correctly designated $PbCO_3 + Pb(OH)_2$.

Experienced analysts usually test white lead to ascertain if it contains the right proportions of hydrate, by first weighing the pigment, then drying it at $212^\circ F.$, followed by roasting it in a dry air current. The water thereby evolved—from 2 to 3 per cent.—is intercepted by a weighed calcium chloride absorption tube. But in the hands of untrained men very

without decomposing. Lead sulphate, if abundant, may be recognised by its needle crystals; and can be further confirmed by its possible reactions.

The best white lead only needs from 11 to 15 parts of linseed oil to render it a satisfactory pigment. White lead paint does not eventually crack in the manner that zinc white and baryta white paints are liable to do. It is believed by many chemists that this admirable trait is due to the saponification of the white lead by the oil used in it; lead linoleate thereby forming.

An interesting experiment bearing on this phase is readily undertaken. Make a thin film of white lead oil paint upon a glass slide, and then add a few drops of dilute sulphuric acid (10 per cent. of acid), and gently stir with a fine glass needle. A creamy state will be produced owing to the decomposition of the lead soap; and the accompanying destruction of its oily or hydrofuge nature. Nothing of the kind follows similar treatment of zinc white and baryta white oil paint. A microscopical examination of this treatment discloses some very beautiful lacy patterns.

It is true that barium sulphate is immune from the attacks of sulphuretted gases and vapours, and thus retains its whiteness, and may confer the same trait on any white lead with which it is mixed; but it is none the less an adul-

No. 1.—About one-thirtieth inch of a layer of newly formed netted particles of lead carbonate; magnified.

No. 2.—About one-thirtieth inch of a layer of starred lead carbonate, being precipitated from solution; magnified.

No. 3.—About one-thirtieth inch of a layer of lead carbonate granules, of which the visible nodules are composed; magnified.

erroneous calculations may be arrived at by the adoption of this method. A very simple experiment will give a clue to the required quality of white lead. When strongly heated it should lose 14.5 per cent. of its weight, owing to the elimination of carbon dioxide, and water. If this result is not obtained, additional tests should be applied to learn the character of the defects.

Although white lead has been found adulterated, either accidentally or intentionally, with many additions, the only ones likely to be encountered are barium sulphate (heavy spar, or barytes) and lead sulphate. Among the substances inadvertently incorporated in white lead are metallic lead—this gives it a greyish tinge; litharge or massicot—this gives it a yellowish tinge; minium or red lead—this gives it a rosy tinge; excess lead hydrate—this makes it translucent; excess lead carbonate, and lead acetate—these do not appreciably alter its appearance. Compounds which have been purposely introduced into white lead include (besides those above referred to) china clay, chalk, and whitening. They are, however, very seldom used, and hardly require testing for unless the white lead is intended for exceptionally valuable work.

For the discovery of barium sulphate or barytes it is only necessary to treat a sample of the white lead with dilute nitric acid, which will completely dissolve the substance if it is pure. Any deposit left will almost certainly indicate barium sulphate or lead sulphate; most probably the former, the minute granules of which will withstand an excess of any kind of acid

teration. Moreover, in view of the fact that white lead, when satisfactorily varnished, is protected against the entrance of such fumes, the claim made on behalf of barium sulphate must be considered to be simply an excuse for its use. Again, since barium sulphate oil paint habitually in time, cracks and peels, white lead containing it might also succumb to the same fault.

The old Dutch method for the manufacture of white lead, modified to suit modern ideas, still seems to yield the most acceptable composition. In this, as many readers will know, metallic lead in rolled sheet, or some other convenient form, is suspended above acetic acid in large jars which are embedded in manure or spent tan, and covered by boards above and around which the same refuse material is built up. After several months' experience the lead is converted into carbonate and hydrate.

The practice in which acetic fumes act as a catalyst or carrier for the CO_2 instead of forming chemical combination, except in the preliminary stages, maybe, is alluded to now because sometimes lead acetate may occur in the white lead. Amounts of lead acetate ranging from 2 to 11 per cent. have been found. To test for this salt, the dry white lead is ground up with distilled water into a paste, which is washed on a filter with freshly boiled distilled water. The filtrate should only be slightly cloudy when dilute sulphuric acid is added to it. Otherwise, if cloudiness is conspicuous, it signifies the presence of lead acetate in the white lead.

Litharge, sodium chloride, and water, agitated together for several hours, and then penetrated by a current of carbon dioxide, till the substance is neutral, precipitates very excellent white lead; but it is liable to become inferior if not properly manipulated. Variations of this process are adopted in many districts. There can be no chance for any lead acetate forming in these grades.

The laboratory method of producing pure lead carbonate is to pass a solution of sodium carbonate into a solution of lead acetate or lead nitrate, until the formation of a precipitate (*i.e.*, lead carbonate) ceases. Such precipitates are worth microscopical examination during their evolution. My own plan is to place a few drops of a solution of sodium carbonate and lead acetate (or lead nitrate) close together on a glass slide, place the latter on the stage of the microscope, and while looking through the tube cause the two solutions to flow into the other by a touch with a needle. The shapes of the particles of instantly, or else rapidly, formed precipitate can then be well observed.

In the case of the lead acetate reaction irregular networks of extremely minute crystals mostly appear. With lead nitrate starred crystals abound. The first are shown in Fig. 1, and the second in Fig. 2. Some of these objects may be detected in solutions of the respective salts before contact with sodium carbonate solution, owing to the action of CO_2 dissolved in the water, or attracted from the air; but their numbers are incalculably augmented when the sodium carbonate solution is added. Both forms are to be found in either solution—acetate or nitrate—at various times, and often minute separate needles accompany them. The stars and needles are heavier than the granules. The interstices between the stars are gradually filled up until angular objects are formed. The continuous deposition upon these, and upon clusters of less shapely crystals, of relays of particles, as shown in Fig. 3, gives rise to the visible nodules, resembling small white seeds, so well known to chemists.

I have found similar nets, stars, and grains in acetated metallic lead while being converted into white lead; and I believe that the lead hydrate, by occupying positions between the granules, which are nucleated by the stars, holds them together through its affinity for surrounding oxygen, without it being able to truly oxidise itself. This idea seems to be confirmed by watching the magnified white lead breaking down under the influence of a dilute acid.

DISTILLATION OF AQUEOUS SOLUTIONS OF RELATED ORGANIC SUBSTANCES.

AT the recent meeting of the British Association at Bournemouth, a paper on this subject was read before the Chemistry Section by Messrs. J. Reilly, D.Sc., and W. J. Hickinbottom.

When dilute solutions of organic fatty acids are distilled, said the authors, it is well known that certain regularities are observed. Various forms of distillation constants have been advanced to express such regularities. These constants may be derived from Nernst's law of distribution. This law may be used as a starting-point for the discussion of the theory of distillation of dilute solutions. For large changes in concentration Nernst's law does not hold exactly, and a method of steam distillation is recommended in which only small changes in concentration occur. By plotting the constants for the normal fatty acids (formic to caprylic acid) against the number of carbon atoms present in the acid, an approximately straight line results, showing an interdependence between molecular constitution and rate of steam distillation. Acids containing a branched carbon chain (as isovaleric) have greater constants than normal acids of the same molecular weight. The experimental evidence at present available shows that for isomeric substances (as, for example, *normal* and *iso* butyric acids), the distillation constants are distinct enough to differentiate between the substances.

The lower saturated monohydric alcohols, phenols, and other substances have been distilled in a current of steam under definite conditions, and results have been obtained showing a relation between molecular complexity and the distillation constants. In cases where the constitution of a substance is uncertain, and when it is volatile in steam, a comparison of its distillation constants with those of allied substances may assist in deciding its molecular constitution. Within certain limits the distillation constants for formic and acetic acids and the lower saturated aliphatic alcohols

are subject to variations depending on the concentration. The addition of certain non-volatile substances, such as acids or salts, also causes an alteration in the distillation constants. As the homologous series of saturated fatty acids and alcohols are ascended, the distillation constants increase with the molecular weights, the reverse of what might be expected from a knowledge of the vapour tension of the pure substances. It is considered likely that the tendency for the acids or alcohols to form molecular complexes may account for this behaviour.

As well as using the method of steam distillation for analysis of fermentation products and various technical preparations containing the volatile fatty acids, a method has been worked out to detect the presence of butter and of fats of the coconut-oil type in margarine and other products. By determining the distillation constants of the water-soluble volatile acids under definite conditions, constants for the fats are obtained which differ considerably in the case of butter fats compared with other fats which have been examined (coconut oil, palm-kernel oil, babassu fat).

DYESTUFFS FROM SWITZERLAND.

DR. E. A. SWIFT, managing director of the Sandoz Chemical Co. Limited, in the course of a letter to the *Yorkshire Post* regarding a statement which had appeared in that journal that "In responsible quarters it is believed that some of the colours emanating from Swiss sources have their origin in Germany, or are the products of firms financed by Germans," asks what are the "responsible quarters." "Is it the Board of Trade," he asks. "If so, perhaps it might be worth while to know why we are now shipping, and have been shipping by a special arrangement with the Board of Trade for nearly five years, the raw material for the manufacture of the dyes which are returned to this country. Why should the Swiss bother to get British and Allied raw material when the colours 'have their origin in Germany'? Further, an arrangement has now been concluded with 'responsible quarters' by which the Swiss agree to take 95 per cent. of their raw materials from Great Britain or Allied countries, with an English official acting under the British Legation in Berne to act as inspector, with access to the works books; no certificate of origin being granted until this official is satisfied of the absolute *bona-fides* of the dye concerned.

"The writer has just returned from Switzerland, and found a brisk demand for Swiss dyes for export from Switzerland to Germany. Why? Because the Germans are finding the same difficulties as everyone else. Plant takes time to re-adapt, raw material is short and will be short, they have lost coal-fields and chemical deposits, production is less; they cannot work miracles. 'Responsible quarters' know very well, wherever and whoever they are, that their exchange arrangement with the Swiss dye industry, raw material for dyestuffs has been and will be a great boon to the textile trade, and one upon which they could well congratulate themselves.

"As regards the dyes 'being the product of firms financed by Germans,' this statement was made on November 21, 1917, and publicly withdrawn as being 'wholly untrue and without foundation.' So far as the statement made by one of your informants regarding the visit of a delegation of the Colour Users' Association is concerned, it can only be said that we do not believe that is a correct description of the true object of their visit, or of the reply they got. Please let it be clearly understood that on that visit no question of any sort relating to any arrangement was put by the delegation of the Colour Users' Association to the Sandoz Chemical Works.

"We would finally state that we have backed England through thick and thin with our supplies since August, 1914, and we feel sure that the other Swiss makers have done the same. We have fought the German competition before the war more strenuously than British makers ever did. We shall still fight it, and we are confident that we can hold our own. It is to the best interests of the British trade that we should do so. We want no favours—simply a fair field—but such statements as those taken up by us in this letter are not fair because they are not true."

COLOURWORKERS' CLAIMS.—A Court of Arbitration at Old Palace Yard, London, on Tuesday heard an application by the National Federation of General Workers for an advance of wages for workers in the paint, colour, and varnish manufacturing trades. The court reserved their decision.

INSTITUTE OF METALS.

AUTUMN MEETING.

THE annual autumn meeting of the Institute of Metals was held at the University, Sheffield, on Wednesday and Thursday. The President, Professor H. C. H. Carpenter, occupied the chair.

The following are abstracts of some of the papers submitted:

"The Ternary Alloys of Tin-Antimony-Arsenic."

By J. E. Stead, D.Sc., M.Met., F.R.S.

The paper contained a short review of a paper read before the Society of Chemical Industry in 1897, on the ternary alloys of tin-antimony and tin-arsenic, in which it was shown that cold alloys containing between 92.5 and 75 per cent. tin and 75 and 25 per cent. antimony contain cuboidal crystals having the composition of Sb_3Sn embedded in a eutectic consisting of a solid solution of 92.5 per cent. tin and 7.5 per cent. antimony; also that cold alloys containing from traces of arsenic up to 5 per cent. and 99.95 per cent. and 95 per cent. tin contain crystals in the form of flat plates which on being separated were found to have approximately the composition of Sn_3As_2 and a matrix of practically pure tin.

The interesting feature of the present paper is the character of the ternary crystals that form when some of the alloys containing tin, antimony, and arsenic solidify. In the slowly cooling alloy containing 70% tin, 25% antimony, and 5% arsenic, more or less complete spherical shells grow, leaving as the matrix the eutectic of the ternary alloy of tin plus antimony which contains only traces of arsenic. If the alloys contain less than 2.5 per cent. arsenic when associated with 25% of antimony and the balance of tin, the crystals formed are cuboidal and not spherical, but when the arsenic exceeds 2.5%, the antimony remaining at 25%, the crystals begin to change from the cubic to the spherical form. It is not till the crystals themselves contain a ratio of arsenic to antimony of more than 1 to 7 that the spherical forms become pronounced, but in every alloy no arsenic remains in the eutectic, for all of it crystallises out in the ternary crystals, whether they are cuboidal or spherical. When the arsenic is maintained at 5%, and the antimony varies, it is not till the antimony exceeds about 8% that the perfectly flat crystals begin to change into segments of spheres. In these alloys the whole of the arsenic is included in the separate crystals, and none remains in the eutectic.

When an alloy containing 70% tin, 25% antimony, 5% arsenic, is very slowly cooled so as to lead to the formation of very large spherical crystals, and the cold alloy is strongly etched, the central portions of the spherical shells resist the attack and remain white, and the crystalline matter enveloping these nuclei, which subsequently fell out of solution, are stained a brown colour. It is further shown that the exterior borders of the complete crystals consist of aggregations of cubes, from which it is evident that the crystals that first form contain more arsenic than those which fall out of solution at a later period.

In an appendix to the paper, the author gave analyses of the fragments of the cleavages from the central portions of the spherical crystal shells, which yielded on analysis 60.15% tin, 27.5% antimony, and 12.45% arsenic. It was impossible to separate the first portions that fell out of solution by chemical means, and it is possible that what was separated mechanically included other portions of the crystals. The analysis just given only proves that these portions contain about twice as much arsenic, or more than what fell out at a later period.

The analysis of the whole crystals approximated to 48% tin, 42% antimony, and 10% arsenic. When 50% of these crystals were melted with 50% of the eutectic of tin-lead, the crystals found on solidification were more or less spherical in form. Crystallised out of the eutectic of lead-antimony, the crystals were also spherical, but other crystals of undeterminate form were also present adhering to the walls of the spherical segments.

The composition of the flat, platy crystals separated from the alloys containing arsenic, constant at 5%, together with 4% and 6% antimony, contained:

Alloys	Yielded crystals in flat plates.
Tin 91%, antimony 4%, arsenic 5%	= Tin 64.3%, antimony 6.2%, arsenic 29.5%.
Tin 89%, antimony 6%, arsenic 5%	= Tin 64.5%, antimony 6.73%, arsenic 28.8%.

In the alloys containing more antimony, from 8% to 10%, the crystals contained:

Alloys.

Yielded spherical crystals.

Tin 87%, antimony 8%, arsenic 5% = Tin 63.63%, antimony 18.27%, arsenic 18%.

Tin 85%, antimony 10%, arsenic 5% = Tin 56.50%, antimony 27.80%, arsenic 15.7%.

It was difficult to calculate the chemical constitution of crystals of such mixed and complex nature. It is evident, however, that until the ratio of antimony to arsenic exceeded 1 to 1 the spherical crystals of pronounced character did not form; on the other hand, cubic crystals did not begin to change to the spherical form until the ratio of antimony to arsenic in the crystals exceeded about 7 to 1.

The alloys are very brittle, cleavage following the central part of sheet crystals. For that reason excepting for the production of ornamental objects, they are of no commercial value. No attempts have been made to explain why idiomorphic spherical crystals should take spherical form and the discussion of this is left until more research has been made.

Notes by Mr. J. L. Spencer on curvature in mineral crystals indicated many causes why the curved faces were produced, but in no case were these crystals truly idiomorphic or developed out of a eutectiferous matrix.

"Second Report of the Beilby Prize Committee of the Institute of Metals, on the Solidification of Metals from the Liquid State."

By Professor Cecil H. Desch, D.Sc., Ph.D.

The present interim report deals with two questions which have arisen in the course of the main investigation, namely, the form of crystal grains and the conditions of cellular convection. If the form of crystal grains were determined by surface tension, as is required by Quincke's hypothesis, they should resemble very closely the cells in a mass of foam. It is shown that foam-cells, whilst variable in shape, tend to resemble the pentagonal do-decahedron. Grains of beta-brass, isolated by means of mercury, are found to be very similar to foam-cells. The polygonal boundaries of crystal grains in plane sections have also been examined, and compared with the theoretical sections of the polyhedra which would be produced by growth from centres under certain assumed conditions. A comparison of the diagrams obtained leads to the conclusion that surface tension has an important share in determining the form of the grain boundaries, although it does not follow that Quincke's assumption of the preliminary separation into two liquids is true. Two forces, that of surface tension and the directive force of crystalline cohesion, are opposed to one another, and their resultant determines the boundary.

The second section describes experiments to determine the difference of temperature between the centre and periphery of a convection cell in a liquid cooling under the conditions of Benard's experiments. Differential thermo-couples of fine wire have been used, and the results show that the difference of temperature may amount to 6° C., or even more in cells of molten wax 18mm. in diameter and about 1.5° in cells of soap solution 30mm. in diameter. Such differences are quite sufficient to account for the preferential freezing at the borders of cells, which is sometimes observed.

"The Properties of Standard Silver, with Notes on Its Manufacture."

By E. A. Smith, A.R.S.M., and H. Turner.

Standard or sterling silver, which contains 92.5 per cent. of silver, and is the only silver alloy of industrial importance, derives its name from the fact that, from very early times, it has been the legal standard alloy for all British silver coinage, and so-called silver plate. Apart from special investigations undertaken for mint purposes, little has been published hitherto on the properties of standard silver in relation to its employment for industrial purposes, and the purpose of the paper is to record a number of tests the authors have made on the metal, and to draw attention to important details to be observed in its manufacture.

When the alloy is cast there is a tendency for the silver to become concentrated in the middle of the ingot, but when proper precautions are taken the differences in composition in different parts of the ingot are not sufficient to interfere seriously with the application of the alloy to minting and to industrial purposes.

The authors have found the temperature of the metal in the crucible when ready for casting to be about 1200° C., and

the temperature of the stream during pouring to be about 1113° C. The best temperature for annealing in works practice has been found to be 670° C. for all-round work. The time necessarily varies according to the thickness of the sheet, but generally annealing is complete in from 20 to 30 minutes. The hardness of the metal at successive stages of cold rolling has been determined, and the results plotted as a graph. The maximum Brinell hardness of standard silver is about 183. The maximum tensile strength varied from 11 to 14 tons per sq. in. according to the method of casting. Results are given for the Charpy impact test, and the Sankey alternating-bend test, which has only recently been applied to non-ferrous metals.

"Graphite and Oxide Inclusions in Nickel Silver."

By F. C. Thompson, D.Met., B.Sc.

As has been shown to be the case in cupro-nickel, the precipitation of graphite from carbonised nickel-silver occurs around the crystals. This graphitisation, which occurs on annealing the metal at temperatures above 700° C., renders the alloy extremely brittle. There is no means of preventing a gradual carbonisation occurring as a result of repeated remeltings of scrap. All that can be done is to dilute the alloy continuously with new metal. Graphitisation occurs first at the surface and thence passes inwards.

Nickel-silver oxidised during melting shows aggregates of small globules of zinc oxide which are not appreciably deformed as a result of subsequent rolling, a fact which enables such inclinations to be differentiated from slag.

ELECTRIC FURNACES.*

By Verdon O. Cutts.

THE development of the electric furnace in recent years is a subject full of interest. It has been intimately associated with the steel industry, and very closely identified with the arc type of furnace in particular. The measure of success with which it has met has awakened keen interest in other industries. The non-ferrous metallurgist has followed this development with considerable interest, and many attempts have been made to adapt it for the melting of brass, copper, and other non-ferrous metals and alloys.

Attempts to utilise furnaces of the arc type for melting metals which readily oxidise and volatilise have resulted in comparatively high metal losses. This feature must obviously exist in any furnace having an intense local heat. Furnaces of this type require constant regulation, which increases labour costs. Electrode breakages and consumption are also a disadvantage. The induction furnace does not possess many of these disadvantages, and has a low current consumption. It is, however, only built of small capacity for non-ferrous work, has a low power factor, and is comparatively very expensive in upkeep, owing to the melting channels requiring frequent renewal. If it is poured dry, it is necessary to start with molten metal from another source.

The type of furnace described is that of the resistance type. It has a high power factor, about 98%, and a load factor closely approximating to this figure. This makes it a very desirable load. The heating element consists of a trough filled with a granular resistor material, and it is the resistance of this material to the passage of the electric current which generates the heat, which is radiated from the furnace roof.

It is a heavily heat insulated furnace, and consequently it is of comparatively large size for its output. This disadvantage is, however, fully compensated for by the fact that, largely due to this particular feature of design, metal losses due to oxidation and volatilisation are reduced to a figure much below that which is possible with any combustion type of furnace. As an illustration of this, the writer recalls an instance in which operating sheets for a six days' run on yellow brass scrap showed actual metal losses of 1.3%. That this was by no means an exceptional or "show" run, has been clearly proved by operating sheets for a subsequent period of six weeks, during which time the over-all metal losses were 0.8113% whilst still working on yellow brass scrap. One feature which is incidental to the reduction of metal losses is the almost total elimination of the danger of occupational disease due to zinc fumes. This fact, taken in conjunction with the heavy heat insulation of the furnace, ensures ideal operating conditions.

* Paper read at the autumn meeting of the Institute of Metals at Sheffield this week.

There are no electrodes in the generally accepted meaning of the term. Carbon blocks are used as a means of obtaining the necessary electrical connection to the material in the resistor trough. As those are not in contact with the atmosphere, there is practically no erosion or electrode consumption. The only parts of the furnace which require renewal and repair are the refractories and the resistor material. Owing to the absence of any intense local heat, the refractories have a long life. The resistor material requires replenishing about once per fortnight under normal operating conditions. No products of combustion are introduced to the furnace.

These furnaces are made in standard sizes ranging from 40kw. up to 1000 kw. and these are of the pit type, hand and motor tilted type, and also of the tapping type. The unit size most generally adopted is the 105kw., round hand tilting type, which has a normal hearth capacity of 1500lb. and a melting rate of 600lb. per hour. The flexibility of this unit is illustrated by the fact that it is operated with charges varying from 5 cwt. up to 2 tons. With regard to the current consumption of furnaces of this type, experience and commercial practice show this to vary from 300 to 350kw. hours per ton of, say, yellow brass scrap melted.

The largest furnaces, say, 500 to 1000kw., are of the rectangular non-tilting or tapping type. The cold charge is introduced through motor operated doors, and rabbling doors are conveniently placed. One of these furnaces, used for remelting aluminium pig, is supplied with 500kw., and has a hearth capacity of 3 tons. The same furnace has a hearth capacity of 9 tons of brass, with a melting rate of 2 tons per hour when supplied with 600kw. A 1000 kw. furnace of this type is employed for melting zinc cathode, and has a capacity of 200 tons per day. Its operating sheets show that the percentage of metal dross averages 2.43%.

It is interesting to note in conclusion that these furnaces are really a development of a considerable number of furnaces of the same type, which are in regular daily operations.

ACTION OF WATER AND ACIDS ON GLASS.

IN testing the stability of various glasses when in contact with water and chemicals, it is customary to powder the glass so as to hasten the solvent effect by increasing the surface on which the water can act. The tests are further conducted in boiling water or at higher temperatures. Both the powdering and the high temperatures are certainly open to objections, and the tests can hardly give comparative results, when they are not performed under the conditions to which the material will subsequently be exposed. That objection is raised against all accelerated tests. In the *Comptes Rendus*, of August 18 last, Paul Nicolardot recommends series of tests, conducted at temperatures of 100°, 120°, 140°, 160° C., such as he performed in 1916; only in exceptional cases would he go to temperatures of 183°, which Mylus uses at the Reichsanstadt, as Nicolardot considers this temperature as altogether excessive. The tests of various French and other glasses, of which he gives particulars, were, however, made after three hours' boiling of the glass, in water or in hydrochloric acid. He takes either whole glass blocks or powdered glass, sifted through screens, which he distinguished as coarse, medium, and fine powders; his figures express the loss of weight in parts per 1,000 parts of glass. The figures were for a Jena glass, whole, coarse, medium, or fine powder respectively, 0.09, 0.25, 0.75, 2.75; for a Krasna glass, 0.44, 4.25, 9, 61.5; these were the best and the worst glasses tested. In the diluted hydrochloric acid the figures for the Jena glass were 0.03, 2, 5, 40; for the Krasna glass, 0.03, 2, 6, 49. Thus the attack increased very much with the fineness of the powder. When the loss of weight is reduced to unit surface, however—so far as this is possible by estimating the surfaces of the powdered particles,—the attack remained fairly constant in the case of water, the increase in the loss of weight suffered by the fine powdering being slight. This is, of course, the argument on which the advocates of the accelerated tests rely. But the argument does not hold for the acid, in which the fine powders all lost two or three times as much in weight as the whole glass, and all more generally than in water. The results are contrary to expectation in two respects. First of all, water is believed to attack the whole glass of glass vessels as much as acid, if not more; and, secondly, one does not see why the fine powdering should have so markedly a stronger influence in the case of the acid, in which, moreover, the difference between the different kinds of glass was far less striking.—*Engineering*.

MECHANISM OF THE "N-BUTYL ALCOHOL AND ACETONE" FERMENTATION PROCESS.*

By J. REILLY, D.Sc., AND W. J. HICKINBOTTOM.

AMONG the more recent applications of bacteriology to technical processes is the conversion of carbohydrates into a mixture of *n*-butyl alcohol and acetone (A. Fernbach and E. Strange, E. P. 21,073, 1913). Certain bacteria are known, as, for example, *granulobacter butylicum*, *bacillus amylobacter*, and the butylic bacillus of Fitz. *tyrothric tenuis*, which, under certain conditions, convert carbohydrates mainly into *n*-butyl alcohol and acetone, producing, in addition, carbon dioxide and hydrogen, together with small quantities of acids and other alcohols (chiefly ethyl). From 100 grammes of maize may be produced 7 grammes of acetone, 16 grammes of *n*-butyl alcohol, 2 grammes of volatile fatty acids, 19 litres of carbon dioxide, and 16 litres of hydrogen at 20°.

In a normal fermentation, which usually lasts about 24-30 hours, the acidity of the mash gradually increases from a very small value until 10cc. of the mash liquor requires from 3.5 to 4.5cc. of 0.1 *N*-sodium hydroxide solution for neutralisation, after eliminating carbon dioxide. Usually 13 to 17 hours are required before the acidity reaches its maximum value, when the formation of acetone and *n*-butyl alcohol commences. The actual value for the maximum acidity and the interval before the *n*-butyl alcohol and acetone are formed depends to some extent on the experimental conditions, the source of carbohydrate, and the percentage of inoculant. During the production of acetone and *n*-butyl alcohol in the mash, the acidity falls gradually to a constant value of about 1.5-2.5cc. of 0.1 *N*-sodium hydroxide per 10cc. of mash. It was considered that, in view of these variations, a study of the acid-formation in the fermenting mash might give an insight into the fermentation process.

The acids present in the mash are principally acetic and butyric acids, with a small quantity of a non-volatile acid. It is found that the ratio of these acids to each other depends on the age of the fermentation. Shortly after inoculating, the acids are present in the proportions of approximately four or five molecules of acetic acid to one of butyric acid, but as the acidity increases the ratio of acetic acid to butyric falls until at the period of maximum acidity there are about 1.1 to 1.4 molecular proportions of butyric acid to one of acetic acid. During the production of the acetone and alcohol the ratio of acetic to butyric acid increases gradually, so that when the fermentation is completed the volatile acids in the mash are four or five parts of acetic and one part of butyric acid.

The fluctuations in the relative amounts of the two acids present in the mash would indicate that the acids are intimately connected with the production of acetone and *n*-butyl alcohol, especially as the formation of the latter substances may be suppressed almost completely by conducting a fermentation in presence of sodium carbonate. Under these conditions the main products formed are acetic and butyric acids. These acids are obtained in the ratio of one molecule of acetic to 1.8 molecules of butyric. Using these proportions, and assuming that *n*-butyl alcohol and acetone are formed from the acids without any appreciable side reactions, *n*-butyl alcohol and acetone should be produced in the ratio of two parts by weight of the former to one of the latter. Such a result is in accordance with the actual yields obtained. It seems likely, therefore, that the *n*-butyl alcohol is produced from the butyric acid. In support of such a view several facts are adduced; the decrease of the amount of butyric acid in the mash is coincident with the formation of *n*-butyl alcohol; the hypothesis is in agreement with experimental data given by Buchner and Meisenheimer (*Ber.*, 1908, 41, 1,410); the reduction of butyric acid to butyraldehyde has been observed to be brought about by certain extracts; the addition of butyric and propionic acids results in the formation of *n*-butyl and *n*-propyl alcohols respectively; *n*-butyric acid has been observed in most fermentations in which *n*-butyl alcohol is obtained.

It is also probable that the acetic acid is an intermediate substance in the formation of the acetone. Since the decrease in the amount of this acid in the mash during the fermentation is much slower than that of butyric acid. The amount of acetone produced is only half that of the alcohol. Also on adding acetic acid to the fermenting mash it is found that the

added acid is converted principally into acetone. The fatty acid is best added periodically some hours after the maximum acidity of the mash has been reached, in such a manner as to maintain a figure for the acidity of the mash equal to the maximum acidity obtained in a normal fermentation.

There is produced also in the fermentation a small amount of ethyl alcohol. It is not yet determined whether this is obtained in a side reaction, or whether it is due to the presence of some impurity.

The two volatile fatty acids in the mash appear to be attacked each in a different manner, the butyric acid undergoing a reducing action, while the acetic acid is condensed to acetone. To account for this difference, it is suggested that the formation of dipropyl ketone by condensation from the butyric acid may be prevented owing to the increased steric hindrance imposed by the presence of large groups.

TREATMENT OF WOOL-SCOURING LIQUORS.

TWO important developments are promised by Mr. W. Russell Grimwade, B.Sc., in *Science and Industry* (Australia), in connection with the handling of wool-scouring by-products. So great is the existence of natural grease in Australian wools that the Commonwealth could provide all the refined lanoline needed for local consumption, as well as the crude fats, and still have 90 per cent. of its production available for export. This result is not at present being obtained, and large quantities are lost in the scouring process.

One problem in the process has been due to the difficulty of obtaining a uniform raw material. The fat derived from the fine wool of merino lambs, if kept separate, requires very little refining; on the other hand, the fats from other wools are so crude that no amount of refining can make them suitable for toilet preparations, and the only useful purpose they can serve is as an ingredient of lubricants and axle greases. Decomposition and fermentation set in if they are kept for any length of time, and such fats should be treated as quickly as possible if intended for use in the manufacture of good products.

Mr. Grimwade states that machines have now been introduced from America capable of continuously treating the enormous volume of scour liquors, and separating from them the small percentage of fat they contain. By this means a fairly uniform and suitable raw material, which may be treated by any one of several well-known processes, should be available to the refiner. In addition to the natural fats that wool contains, there is present a fair proportion of alkali. The scouring is done with soda, which saponifies fat and degreases the wool fibre. A recent discovery promises important developments in this industry. Under the new process, the potash contents of the wool are made to combine with the natural fatty acids, and so create a true soap in the form of an emulsion, which may itself be used as a detergent for a subsequent scouring operation.

These developments may have far-reaching consequences, as any economy in the cost of scouring, either by utilising the waste products or reducing the quality of alkali necessary in the process, will encourage the handling of the wool before shipment.

CRYSTALS.

ARTIFICIAL crystals of great regularity and clearness and of almost unlimited size are claimed as products of the perfected process of R. W. Moore, an American physicist. The usual growing of crystals consists in evaporating the solution in which a little crystal is suspended as a nucleus. In the new method the solution is kept slightly supersaturated, and the growth continues as long as this condition is maintained. Crystals of Rochelle salt (sodium-potassium tartrate) more than three inches long and two inches thick have been produced with all surfaces and angles perfect. This salt is most soluble in hot water, and supersaturation is obtained by dissolving in hot water and slightly cooling. With the aid of a thermostat the temperature is so regulated as to keep up the supersaturated condition. The seed crystal is suspended in the solution of the material, and growth is said to continue indefinitely with efficient control.

* Paper read before the Chemistry Section of the British Association at Bournemouth.

NEWS FROM THE ANTIPODES.

[FROM OUR OWN CORRESPONDENT.]

SYDNEY, August 8.

The Sheep Dip Embargo.—Speaking on this subject recently, Dr. J. F. Elliott, managing director of Elliott Brothers, Limited, expressed the opinion that the recent action of the Federal authorities in prohibiting the importation of sheep dips was quite unnecessary. Pastoralists should have an absolutely unrestricted choice in the treatment of their flocks, and local manufacturers could compete on perfectly level terms with importers. Sufficient protection was afforded by the heavy freights and other shipping charges, together with the cost of keeping stocks. The greatest protection, however, he affirmed, was the scientific knowledge of the Australian manufacturers, coupled with their familiarity with local conditions. So long as "dumping" was prevented, and the cost at port of shipment was not below that which prevailed in the country of origin, the competition from overseas could be welcomed, not feared. The action taken in Melbourne seemed to him quite unjustified, and the explanation so far supplied could not be considered as in any way adequate.

Commercial Alcohol.—A proposition has been put before the Minister for Customs on behalf of a syndicate representing a large amount of Australian capital for encouraging the manufacture of commercial alcohol for industrial purposes, as advocated by the Bureau of Science and Industry. The new motive fuel, which is known as "Natalite," is largely manufactured in South Africa, and it is claimed that it is in every way superior to petrol, and can be sold much cheaper. It is manufactured from sorghum. It is proposed to start the industry in Papua, if the Government will remit the high duty which would have to be paid before it could be brought into the Commonwealth. Another proposal is to utilise the prickly-pear lands of Queensland, the pear itself containing sufficient alcohol to pay for the clearing of the ground for sorghum crops. The syndicate contemplates the provision of up to £500,000. capital for the industry, which it hopes to have in full swing in two years. The Minister has asked to be supplied with full details of the scheme, stating that if the proposition is as hopeful as indicated, the Federal Government will consider the possibility of assisting it.

New Zealand Phosphates.—The only deposit of rock phosphate worked in the Dominion of New Zealand is that at Horseshoe Bush estate, Clarendon, Otago, but phosphate has been discovered in other localities also—for instance, at Milburn, where it has been found in workable quantities; at Wangapeka, Nelson (discovered in 1885, and containing about 45 per cent. of tricalcic phosphate); at Weka Pass (coprolites discovered in 1887, containing 37 per cent. tricalcic phosphate); at Oamaru and at Flagstaff Hill, near Dunedin (coprolites); at Whangarei (where in 1906 a rock was found which was almost pure phosphate of lime), etc.

Meggitt, Limited.—The balance-sheet of Meggitt, Limited, Sydney, shows a net profit for the year ended May 31 of £21,236., against £67,627. for the previous term. The sum available for distribution with the amount brought forward from the previous year makes £63,197. The interim dividend at the rate of 10 per cent. per annum on all shares, and a bonus at the same rate on all ordinary shares, paid in January, absorbed £9,469. A bonus issue of 59,752 shares of 10s. each took £29,876., leaving £23,852. A further dividend on all classes of shares at the rate of 10 per cent. per annum and a bonus at the rate of 10 per cent. per annum on the ordinary shares has been recommended, and will account for £9,469., leaving £14,383. to be carried forward.

Chemical Market.—Values of chemicals generally are firm in the local market, and several lines are reported as scarce. Caustic soda, 76 per cent., is quoted at £26., but English brands are scarce, and holders ask £30. Stocks of soda ash are getting low, although the quotation has not risen above £14. a ton. Bicarbonate of soda remains steady at £15. 10s., and cream of tartar at 3s. The quotation for calcium chloride is £18., and for liquid silicate £21. In acids, business has been done with both citric and tartaric at 3s. 6d. Supplies of arsenic are becoming low, owing to the hold-up of shipping from Melbourne, whence most of the Australian supplies come. The present quotation for white is £65., and for grey £5. lower. There has been of late a better inquiry for cyanide at 1s. 2d. and 1s. 3d. for low grade, according to quantity, the lower price being asked for parcels of a ton or more. High-grade lots are sold according to parcel on the basis of

1s. 1d. per lb. for large quantities and 1s. 2d. for smaller parcels. Zinc shavings, which are used in conjunction with cyanide in mining operations, are quoted at 1s. 3d. per lb. for half-ton lots or over, and 1s. 4d. for smaller parcels. Stocks of each are fairly plentiful. G grade rosin is much firmer at £37. 10s., and N grade at £42. Turpentine is quoted at 7s. 4d. per gallon for pinetree and 7s. 6d. for Pratt's, while linseed oil is firm at 8s. 10d. for raw and 9s. for boiled. White lead is unchanged. In oils generally fair business is being done.

SCOTTISH SHALE OIL DISPUTE.

WITH reference to the report which has been issued to the Press, presumably by the representatives of the Federation of Shale Oil Workers, Scottish Oils, Limited, the new company which has been formed to take over the shale oil companies, draw attention to the fact that a very important omission has been made in this report—viz., that at the meeting between the company and the labour representatives it was pointed out that it had been found by a careful investigation of the accounts that, owing to (1) the payment of the Sankey award of 2s. per day, entailing an additional working charge of over £200,000. per annum, and (2) the advance of 6s. per ton in the price of coal since July 15, entailing a further additional working charge of £215,000. per annum, the industry was now being worked at a loss of about £190,000. per annum, not allowing for depreciation or any return on capital. The demand of the workers was that the working day should be reduced from eight hours to seven hours, which would have entailed a further large loss.

The board of Scottish Oils, Limited, while desirous of meeting the views of the shale oil workers to the fullest extent in their power, pointed out the impossibility of carrying on the industry under these conditions, and if the terms of the miners were insisted upon there would be no alternative but to close down the industry of shale mining, much as this result was to be deplored. As an alternative, however, the board offered to continue working on the present conditions—which include the Sankey award of 2s. per day—until the end of the year, when the company would be in a better position to judge as to the extent of the economies that would be effected by the amalgamation which has just been carried through, and as to how far they would be in a position to meet the demands of the workers. This offer has now been declined.

GERMAN DYES IN THE UNITED STATES.

THE announcement that the United States Government have decided to permit the importation into that country of German dyes for a period of six months has afforded an opportunity to an influential German newspaper to repeat some of the arguments which have been used at different times during the past five years concerning the alleged impossibility of the Allied countries to produce certain classes of dyes.

The decision of the United States in this matter, it is said, shows that an economic war after the war is not thought of, but that efforts are increasing to resume the former normal economic relations with Germany. But it is considered to be very instructive to find that notwithstanding all promises and announcements the production of dyes, carried on during the war with the aid of German patents and works seized by the Allies, and partly with the assistance of very high State subsidies, has so far not succeeded in eliminating German products. What have been produced in Allied countries, the newspaper remarks, are makeshifts, as the production is scientifically and practically only in a state of development, and in any case has not fulfilled during the war the expectations entertained in Allied countries. This was clearly shown some time ago when the consumers of dyes in Allied and associated countries, so long as they possessed no German products, were compelled to have recourse to Switzerland for all the finer and complicated dyes, which country temporarily occupied a position of monopoly.

It is admitted, however, that the dyestuffs industry in Allied countries will develop gradually and reach a high level which can prejudice the future world situation for German products; yet German technique and science, the newspaper concludes, will not be at a standstill, but will ensure for German goods their position in line with the manufacturers of other countries.

AMERICAN IMPORTS OF CHEMICAL PRODUCTS.

THE War Trade Board Section of the United States Department of State announces (Ruling 825, dated August 15) that General Import Licence PBF 37 has been revised and extended, effective August 15, 1919, so as to permit the free importation, without individual import licences, of pig-tin and all metal alloys containing tin, and all drugs and chemicals except those dyestuffs and other articles enumerated below. As now amended, General Import Licence PBF No. 37 authorises the importation into the United States from all countries of the world, except Hungary and those parts of Russia under the control of the Bolshevik authorities, of all commodities except the following commodities, the control of whose importation by individual import licences is desirable: The products described in Groups I., II., and III., and all products derived directly or indirectly from coal tar, including crude products and intermediate products, as well as dyestuffs, medicinals, and other finished products, and including mixtures and compounds of such products and other products:—

Group I.—Acenaphthene, anthracene having a purity of less than 30 per cent., benzole, carbazol having a purity of less than 65 per cent., cumol, cymene, fluorene, methylantracene, methylnaphthalene, naphthalene having a solidifying point less than 79° C., pyridin, quinolin, toluol, xylo, dead or creosote oil, anthracene oil, pitch of coal tar, pitch of blast-furnace tar, pitch of oil-gas tar, pitch of water-gas tar, crude coal tar, crude blast-furnace tar, crude oil-gas tar, crude water-gas tar, all other distillates of any of these tars which on being subjected to distillation yield in the portion distilling below 190° C. a quantity of tar acids less than 5 per cent. of the original distillate, all mixtures of any of these distillates and any of the foregoing pitches, and all other products that are found naturally in coal tar, whether produced or obtained from coal tar or other source.

Group II.—Acetanilid not suitable for medicinal use, alphanaphthol, amidobenzoic acid, amidonaphthol, amidophenetol, amidophenol, amidosalicylic acid, aminoanthraquinone, aniline oil, aniline salt, anthraquinone, arsanilic acid, benzaldehyde not suitable for medicinal use, benzalchloride, benzanthrene, benzidine, benzidine sulphate, benzoic acid not suitable for medicinal use, benzoquinone, benzoylchloride, benzylchloride, betanaphthol not suitable for medicinal use, brombenzole, chlorbenzole, chlorophthalic acid, cinnamic acid, cumidin, dehydrothiolutidin, diaminostilbene, dianisidin, dichlorphthalic acid, dimethylanilin, dimethylamidophenol, dimethylphenylenediamine, dinitrobenzole, dinitrochlorbenzole, dinitronaphthalene, dinitrophenol, dinitrotoluol, dioxynaphthalene, diphenylamine, ethylbenzyl aniline, hydroxyphenylarsinic acid, metanilic acid, methylanthraquinone, naphthylamine, naphthylenediamine, nitraniline, nitroanthraquinone, nitrobenzaldehyde, nitrobenzole, nitronaphthalene, nitrophenol, nitrophenylenediamine, nitrosodimethylaniline, nitrotoluol, nitrotoluylenediamine, phenol, phenylenediamine, phenylolhydrazine, phenylnaphthylamine, phenylglyccoll, phenylglyccoll - orthocarboxylic acid, phthalic acid, phthalic anhydride, phthalimid, resorcin not suitable for medicinal use, salicylic acid and its salts not suitable for medicinal use, sulphanilic acid, thiocarbanili, thiosalicylic acid, tetrachlorphthalic acid, tetramethyldiaminobenzophenone, tetramethyldiaminodiphenylmethane, toluol sulphochloride, toluol sulphamide, tribromphenol, toluidin, tolidin, toluylenediamine, zylidin, or any sulpho-acid or sulpho-acid salt of any of the foregoing, or of any of the products provided for in Group I.; all other products by whatever name known which are employed in the manufacture of any of the products provided for in Group II. or III., and which are obtained, derived, or manufactured in whole or in part from any of the foregoing or from any of the products provided for in Group I.; anthracene having a purity of 30 per cent. or more, carbazol having a purity of 65 per cent. or more, metacresol having a purity of 90 per cent. or more, naphthalene having a solidifying point of 79° C. or above, orthocresol having a purity of 90 per cent. or more, paracresol having a purity of 90 per cent. or more; all distillates of coal tar, blast-furnace tar, oil-gas tar, and water-gas tar which, on being subjected to distillation, yield in the portion distilling below 190° C. a quantity of tar acids equal to or more than 5 per cent. of the original distillate; all mixtures, including solutions, consisting in whole or in

part of any of the foregoing, except sheep dip and medicinal soaps.

Group III.—All colours, dyes, or stains whether soluble or not in water, colour acids, colour bases, colour lakes, leuco-acids and leuco-bases whether colourless or not, indoxyl and indoxyl compounds; ink powders; photographic chemicals; acetanilid suitable for medicinal use, acetphenetidin, acetyl salicylic acid, antipyrine, benzaldehyde suitable for medicinal use, benzoic acid suitable for medicinal use, betanaphthol suitable for medicinal use, phenolphthalein, resorcin suitable for medicinal use, salicylic acid and its salts suitable for medicinal use, salol, and other medicinals; sodium benzoate; saccharin, methylsalicylate, coumarin, and other flavours; synthetic phenolic resin and all resinlike products prepared from phenol, cresol, phthalic anhydride, coumarene, indene, or from any other article or material provided for in Group I. or II., all of these products whether in a solid, semi-solid or liquid condition; synthetic tanning materials; picric acid, trinitrotoluol, and other explosives except smokeless powders; all the foregoing when obtained, derived, or manufactured in whole or in part from any of the products provided for in Group I. or II.; natural alizarine and natural indigo, and colours, dyes, stains, colour acids, colour bases, colour lakes, leuco-acids, leuco-bases, indoxyl, and indoxyl compounds obtained, derived, or manufactured in whole or in part from natural alizarine or natural indigo; natural methyl salicylate or oil of wintergreen or oil of sweet birch; natural coumarin; and all mixtures, including solutions, consisting in whole or in part of any of the articles or materials provided for in this group.

All applications for licences to import dyes, intermediates, derivatives of coal tar, synthetic organic chemicals and drugs, and all other commodities enumerated in the foregoing, must be accompanied by supplemental information sheets giving complete specifications of the character of the commodity proposed to be imported. Such supplemental information sheets are procurable from the Bureau of Imports, War Trade Board Section, Department of State, Washington, D.C.

Collectors of Customs and United States Consuls abroad have been instructed that certificates of non-enemy origin (Consular Form 235) are no longer required for any commodity whatsoever, but the supplemental information sheet referred to in the preceding paragraph must in each case contain such information as will enable the War Trade Board Section to determine the actual origin of the goods.

UNITED ALKALI COMPANY'S FLINT WORKS.

CONCERN has been felt this year by the people of Flint and district in regard to the United Alkali Company's works at Flint. The company have been dismantling the works for some time. The Mayor of Flint (Alderman H. Powell) has now received a letter from Mr. Max Muspratt, chairman of the United Alkali Company, Ltd., in reply to the representations of a deputation from the Flint Town Council.

The letter states that the company have completed the arrangements by which Courtaulds, Limited, acquire the whole of the works at Flint, that substantial developments will no doubt be made, and that the prosperity of Flint will in no way suffer by the transfer. The letter further states that Flint has ceased to be the best district for heavy chemicals, and that the company have had to recognise that fact. It is a great pleasure that they can do so without the community of Flint having to suffer in any way.

LEVER BROS. AND PRICE'S PATENT CANDLE COMPANY.

THE terms of the offer to purchase the shares of Price's Patent Candle Company, Ltd., were announced in a circular issued on Monday. Lord Leverhulme offers, under a contract which was signed on that day, to purchase the shares at a price equivalent to £106. per share, £40. being payable in cash and the balance by the allotment of thirty-two 15 per cent. "A" cumulative preferred ordinary shares of £1. each in Lever Brothers, which, at the present market quotation of £2. 1s. 3d., are worth £66. The offer is contingent upon holders of at least 90 per cent. of the shares of Price's Candle Company accepting it. The capital of the company consists of £600,000., divided into shares of £10. each. If the whole of the shares are sold to Lord Leverhulme, the transaction will involve a sum of £3,975,000.

ESTIMATION OF METALLIC ZINC CONTENT OF ZINC DUST.*

By W. F. EDWARDS.

By using the Franz Meyer apparatus and observing all of the numerous required details one can obtain quite accurate, consistent results in the chemical analysis of new (unused) zinc dust; and by the exercise of proper care and precautions fairly consistent results can be obtained also on zinc dust that has been used in the process of sherardising.

However, taking everything into consideration, the hydrogen gas method is not suited to the estimation of zinc dust, used or unused, in sherardising. It requires too long a time, too much attention to details, and too much apparatus. Barometer readings, temperatures, vapour tension corrections, gas absorption corrections, etc., are necessary.

The method of estimating the metallic zinc in zinc dust by the reduction of potassium iodate in dissolving the zinc dust in a strong solution of fixed alkali and subsequent titration of iodine distilled from the acidified solution by sodium thiosulphate, in the main as given in the second edition of "Merck's Reagents, Their Purity and Tests," gives consistent results when proper attention is given to a number of details such as continued shaking during the solution of the zinc dust, proper cooling of the solution of potassium iodide in which iodine is absorbed when distilled from the acidified solution, and proper attention to connections in and displacement of the air from the distillation apparatus. This method, like the hydrogen gas method, is subject to too many details to be a good working method in sherardising or other commercial plants.

Amalgam Method.

The amalgam method gives very uncertain results, but in general it may be said to give too high percentages of zinc oxide, and therefore by difference too low percentages of metallic zinc. As usually described, the amalgam method depends on the titration of the excess of a measured quantity of standard acid, usually hydrochloric acid. It is not easy to get a definite end reaction in an acid solution containing zinc salts, as the zinc hydroxide formed does not show sharply enough the point at which the acid is neutralised by the standard alkali solution. By titrating the acid solution of zinc salts with standard solution of potassium ferrocyanide to obtain the zinc directly instead of by deduction from the amount of acid used, one can get a definite enough end reaction for practical purposes, if the solution is filtered before titration. However, the amalgam method can only be of value when carried out with careful attention to details in parallel estimations of the "unknown" zinc dust and standard zinc dusts of known metallic zinc content, under identical conditions of reagents, temperature, and time. Even under such conditions the results are not even satisfactory for ordinary practical purposes.

Ferric Ammonium Alum Method.

The method of reduction of ferric sulphate in my hands gave very inconsistent results, even when care was taken to run parallel estimations as nearly in the same way as practical. However, with crystallised ferric ammonium sulphate (ferric ammonium alum) I was able to get very satisfactory results, both as to consistency and accuracy, the results comparing favourably with those obtained by the hydrogen gas method, the time being approximately 15 mins. instead of from 6 to 36 hrs., the approximate time limits for the gas method. The process is satisfactory when 1 grm. of zinc dust is weighed into a 600cc. Erlenmeyer flask and 50 grms. of the ferric ammonium alum in crystals (the larger the better) and 100cc. of water added. The mixture should be kept in constant stirring motion by giving a suitable motion to the flask. The crystals of ferric alum aid in stirring the zinc dust, and will usually not all be in solution when the zinc dust is dissolved. As soon as the zinc dust is all dissolved add 100cc. of 1 to 10 sulphuric acid and titrate with N 10 potassium permanganate solution. In case there are many analyses to be made it saves calculation to use a potassium permanganate solution each cubic centimetre of which represents 1 per cent. of zinc on a 1 grm. sample.

Comparison of Results.

The results are quite accurate enough for the estimation of the metallic zinc content of used or unused zinc dust in sherardising plants. The following analyses of used and unused zinc dust by the hydrogen gas method and the ferric

ammonium alum method were made from the same sample in each case, and show a very close comparison:

NEW ZINC DUST.

Hydrogen Gas Method.		Ferric Alum Method.	
No.	Per Cent.	No.	Per Cent.
No. 1	94.9	No. 1	94.7
No. 2	94.9	No. 2	94.7
No. 3	94.8	No. 3	94.6
No. 4	95.1	No. 4	94.5
No. 5	95.3	No. 5	94.6
Average	95.0	Average	94.8

USED ZINC DUST.

Hydrogen Gas Method.		Ferric Alum Method.	
No.	Per Cent.	No.	Per Cent.
No. 1	79.4	No. 1	79.7
No. 2	78.8	No. 2	79.6
No. 3	78.6	No. 3	79.7
No. 4	79.5	No. 4	79.8
No. 5	78.4	No. 5	79.8
Average	78.9	Average	79.7

In the case of the hydrogen gas method on used zinc dust I was unable to get a completed reaction in less than 24 hrs., the time being more often 36 hrs. Attempts to speed up this method by using stronger acid than usual led to freak speeds that gave unsatisfactory results. I have not made any attempt to explain the freaks.

On the whole, I think I am justified in stating that the ferric ammonium alum method of estimating the metallic zinc content of both used and unused zinc dust is quite satisfactory for all practical purposes.

AMERICAN PRODUCTION OF SODA COMPOUNDS.

THE following table, taken from the preliminary report on the Mineral Resources of the United States in 1918, issued by the Geological Survey of that country, gives details of the domestic output of sodium and sodium salts in 1917 and 1918.

Salt.	1917.		1918.	
	Quantity (short tons)	Value.	Quantity (short tons)	Value.
Sodium acetate	1,919	\$225,828	2,542	\$447,897
Sodium benzoate	—	—	203	\$86,058
Sodium bicarbonate	119,177	4,029,499	118,535	3,293,153
Sodium borate	—	—	571	438,750
Sodium carbonate	1,399,625	38,028,000	1,399,628	35,635,520
Soda ash	—	—	—	—
Monohydrate and sesquihydrate	55,035	1,202,875	22,478	482,068
Salt soda	77,959	1,698,520	82,215	2,014,021
Sodium chloride and sodium perchlorate	3,915	1,333,426	2,113	1,094,250
Sodium chloride (common salt)	—	—	—	—
Salt in brine	2,890,588	1,083,586	2,830,600	1,245,265
Rock salt	1,005,025	3,897,595	1,633,341	5,884,661
Evaporated salt	2,182,564	14,359,261	2,724,203	20,010,455
Sodium chromate and sodium bichromate	22,116	3,045,133	28,334	9,808,118
Sodium cyanide, sodium peroxide, and metallic sodium	11,201	7,705,300	9,341	5,514,437
Sodium ferrocyanide	4,173	2,577,667	1,325	2,090,410
Sodium fluoride, sodium fluosilicate, and sodium fluoride	1,424	397,305	788	655,705
Sodium nitrite	861	180,145	1,701	609,779
Sodium hydroxide (caustic soda)	488,056	29,102,689	513,363	31,854,470
Sodium phosphate (including all sodium phosphates)	13,305	711,283	15,020	1,427,847
Sodium silicate	251,011	3,317,547	317,161	5,870,973
Sodium sulphate	—	—	—	—
Salt cake	183,500	2,87,041	140,907	2,835,125
Glauber's salt	47,735	722,465	50,233	1,027,581
Nitre cake	387,824	780,278	142,405	301,562
Sodium sulphide	49,494	1,305,473	43,490	2,263,394
Sodium sulphite and sodium bisulphite	13,707	300,668	16,362	478,482
Sodium tetraborate (borax)	320,890	4,717,532	26,673	3,909,565
Sodium thiosulphate (hyposulphite)	26,598	717,924	26,868	1,054,025
Miscellaneous sodium salts	56	40,000	386	1,158,035
	1,164,925	132,787,578	10,196,347	142,979,761

NEW CHEMICAL WORKS AT SELBY.—The Selby (Yorkshire) Urban District Council have approved the plans for a new factory in The Holmes, at Selby, to be erected by the Selby Chemical Company, Ltd.

* Chem. and Met. Eng. (New York)

ITEMS OF INTEREST.

STORAGE OF CALCIUM CARBIDE.—A fine of £3 was imposed on the Severn Engineering Company, Worcester, on Tuesday, for keeping 10cwt. of calcium carbide without a licence.

EXPLOSIVES IN COAL MINES.—The Home Secretary has made an order repealing so much of the schedules to the Explosives in Coal Mines Orders of February 10, 1914, and June 22, 1914, as relates to the explosives monarkite and stomonal No. 1 respectively.

OBITUARY.—The death occurred on Thursday of last week of Mr. F. E. Lott, a member of a firm of analytical chemists to the Burton Corporation, and who was closely identified with the public work of the borough in various forms. He was 64 years of age, and was an authority on the brewing water of Burton-on-Trent.

MALAY STATES TIN EXPORTS.—It is reported officially from Kuala Lumpur that the August exports of tin from the Federated Malay States amounted to 2,955 tons, compared with 3,756 tons in July and 3,259 tons in the corresponding month last year. For eight months of the present year the exports amounted to 25,100 tons against 25,170 tons in 1918, and 26,418 tons in 1917.

GOVERNMENT-AIDED SVELTER WORKS IN AUSTRALIA.—Mr. Hughes, Australian Prime Minister (*Reuter's* Melbourne correspondent telegraphs), has stated in the House of Representatives of the Commonwealth that the Imperial Government have promised to advance £500,000. for the purpose of fostering the treatment of spelter in Australia, and the Commonwealth will also assist in the establishment of similar works.

REPORTED PURCHASE BY LEVER BROTHERS.—It is reported that negotiations are in progress for the purchase by Messrs. Lever Bros., Limited, Port Sunlight, of the big works erected on the Pembrey Burrows during the war for the manufacture of explosives by Messrs. Nobel, Limited. The works employed during the war something like 7,000 people; they are of vast extent, and would, it is stated, be utilised by Messrs. Lever Brothers for the manufacture of soap and margarine.

CAPITAL ISSUES.—The Treasury announce that applications for permission under the Defence of the Realm Regulation 30 F. to raise capital in this country where the proceeds of the issue are to be applied for capital purposes outside the United Kingdom will in future be dealt with by the Board of Trade. All communications with regard to either new or pending applications should be addressed to the Secretary, Capital Issues Committee, Board of Trade, Gwydyr House, Whitehall, London, S.W.1.

OIL-BORING IN SCOTLAND.—The boring for petroleum on the Scottish shale oilfield, on the borders of Edinburgh and Linlithgow, has been stopped. The expert workers from the United States have returned home, it being stated that their contract was completed. The work has been in progress for several months, and the progress was slow, whinstone being encountered under the shale bed. It is not officially conceded that oil-boring has been abandoned, but, it is stated, those with experience on the Scottish shale oil area do not believe there is any flow of oil, and that the only method of extracting oil is by the process conducted by the companies on the Mid and East Lothian shale fields of raising the shale, and thereafter extracting the oil in the surface retorts.

GERMAN SYNTHETIC NITRATE PLANTS.—Writing in the *Journal of Industrial and Engineering Chemistry*, Mr. R. E. McConnell says that during the year ended November 1, 1918, the Oppau plant produced 20,000 long tons of fixed nitrogen by the Haber process. That is to say, the capacity of the plant is equivalent to approximately one-fifth the total of 3,000,000 tons of sodium nitrate furnished by Chili to the entire world during the same period. It is reported that a similar plant, which has a rated capacity of 125,000 tons of fixed nitrogen per year, has been constructed near Halle. If this is true, Germany's total capacity of 215,000 tons of combined nitrogen, by the Haber process, is equivalent to one-half of the total world's consumption of Chili nitrate. It had been stated that nitrogenous products manufactured in Germany in the year 1916 contained 130,000 tons of combined nitrogen, an amount equivalent to 2,500,000 tons of sodium nitrate, which is practically equal to the total tonnage annually mined in Chili for the markets of the entire world. Germany is now in a position to export nitrogenous products in amounts that approximate her normal consumption of 750,000 tons annually.

ZINC AND ZINC DUST PRICES.—There is no change to report in the price of Australian high-grade zinc dust (88/92% metallic zinc), which remains at £68. to £70. per ton, c.i.f. U.K. Inquiries are fairly numerous, being mostly for forward shipment from Australia. The price of Australian electrolytic zinc, containing 99.95% metallic zinc, is unchanged at £42. per ton, f.o.b. Australia, for direct shipment to New Zealand, India, South Africa, and the Far East.

ZINC-COPPER ALLOY.—"Biakmetal," the new zinc-copper alloy of Adolfo Pouchain, an Italian engineer, is claimed to be stronger than steel and less corrosive than copper, its chief qualities being the highest known breaking point, highest limit of elasticity, perfect homogeneity, and high resistance to heat and chemical action. It can be cast, turned, drawn, forged, rolled, and stamped. It can be substituted for steel, brass, and aluminium, and is claimed to have important advantages over these metals for certain uses.

MUNITIONS CONTRACTS.—The Minister of Munitions has appointed a Committee, under the chairmanship of the Financial Secretary to the Ministry, for the purpose of expediting the liquidation of contracts in all Departments of the Ministry, and also to ensure greater co-ordination between the Liquidating and Accounting Departments and their associated services. The Committee will consist of:—Mr. James F. Hope, M.P., chairman, and Mr. M. Webster Jenkinson, O.B.E., Mr. J. L. Coates, and Mr. E. A. Watson, O.B.E. The Minister has delegated to the Committee full authority for dealing with the liquidation of contracts. Complaints as to delay in liquidation will be considered by any of the three members of the Committee.

SWISS DYE PRECAUTIONS.—The secretary of the Manchester Chamber of Commerce has been supplied by the Swiss Legation, London, with a copy of an order of the Swiss Department of Public Economy, made on June 26 last, remitting the issue and the visa of certificates of origin for aniline colours to the control of the Basle Chamber of Commerce. Certificates of origin as to these colours, if not emanating from that Chamber, but from other issuing offices, should bear the following words: "Délivré sur la base d'une facture visée par la Chambre de Commerce de Bâle." The Legation explain the system of export from Switzerland as follows: In order to prevent the export of foreign products under the Swiss flag, it is absolutely necessary that the origin of these goods should be controlled. As the aniline colour industry is concentrated almost exclusively in the neighbourhood of the Basle Chamber of Commerce, and as that Chamber possess a wide experience in this connection, the Department of Public Economy have now deemed it expedient to make the order quoted above. The control exercised by the Basle Chamber of Commerce affords an adequate guarantee that no productions of the colour industry of any country other than those of Switzerland will benefit by a Swiss certificate of origin.

PROPOSED "MADE IN U.S.A." TRADE MARK.—The *Board of Trade Journal* reports that the Merchants' Association of New York has sent to members of Congress and other Federal officials a brief in opposition to the Bill which authorises the adoption, registration, and protection of a national trade mark to distinguish merchandise produced in the United States. The memorandum claims that the Bill will not bring about the results which it aims to produce, and that its operation will injure, instead of promoting, trade with foreign nations. Although the general use of a suitable legend showing the origin of merchandise, such as "Made in U.S.A.," accompanied by a suitable emblem, is favoured by the association, the memorandum dwells on the legal obstacles which will be encountered. The chief is the practical difficulty of determining and enforcing the standards to be followed in licensing or refusing to license houses to use the trade mark. Again, objections are raised to the granting of too much responsibility and authority to one man—the Secretary of Commerce—in enforcing the provisions of the Act. It is stated that the power which the Act would give to the Secretary of Commerce is dangerous, inasmuch as it would give him complete control over the business of persons engaged in foreign trade. He would also encounter difficulties in fixing and enforcing standards based upon the grades and accepted traditions of manufacturers and trade associations in the United States by the necessity of interpreting and considering at the same time the standards of a large number of foreign countries in each of which the standards and traditions vary. The attempt to establish and enforce standards, therefore, would be sure to injure American sellers or offend foreign powers.

GOVERNMENT AND THE BRITISH DYE-STUFFS CORPORATION.—Mr. Harry Spivey, the president of the Heckmondwike (Yorks.) Chamber of Commerce, made a strong complaint at a meeting of the Chamber a few days ago, concerning the extent to which existing regulations are handicapping country dyers and manufacturers who do their own dyeing. Mr. Spivey pointed out that although the British Dyestuffs Corporation and other firms had succeeded in producing several dyestuffs formerly made only in Germany, it could not be maintained that these were produced in adequate quantities to meet the country's requirements. He alleged that the British Government were bent upon the creation in this country of a monopoly in favour of home producers of dyestuffs, while they were themselves the largest shareholders in the British Dyestuffs Corporation, along with the largest Yorkshire syndicate of dyers. Unfortunately, country dyers and manufacturers were at their mercy. Unless British textile manufacturers were supplied with German dyestuffs they could not maintain the quality of the colouring essential for their success, and would be hopelessly handicapped in their competition with America.

LEGAL INTELLIGENCE.

Customs Seizure of Pyrogallie Acid.

The action *Brown v. Buckley*, which came before Mr. Justice Greer, in the Vacation Court, on Wednesday, was a motion by the plaintiff for an injunction to restrain the defendant, his servants or agents, pending the trial of the action, from detaining 5cwt. of pyrogallie acid, the property of the plaintiff, and from acting in respect of the same upon or under a Royal Proclamation, prohibiting the importation of the goods, purporting to be made under section 43 of the Customs Consolidation Act, 1876, by virtue of which the defendant claimed to detain the goods in question.

Mr. R. A. Wright, K.C., in opening, read an affidavit which said that the plaintiff was a dealer and importer of chemical materials, carrying on business in London and Manchester, as Brown and Forth, and the defendant was an officer of Customs. In May, 1919, the plaintiff ordered 5cwt. of pyrogallie acid from the Mallinckrodt Chemical Works, Limited, of Montreal, Canada. The consignment was shipped on the s.s. *Bevie* at New York about July 29, and arrived at Manchester about August 17. By a notice of seizure dated August 29, the defendant, who was an officer of Customs and Excise at Manchester, purporting to act under the Customs Consolidation Act, 1876, informed the plaintiff that the Commissioners of Customs and Excise, by virtue of their powers under the Customs Acts, seized the goods in question as forfeited on the ground that they had been imported into the United Kingdom in contravention of a Royal Proclamation prohibiting their importation except under licence of the Board of Trade.

Mr. Wright submitted that the Executive had no power to issue any such prohibition as they purported to do here. It followed that the seizure of the goods was a wrongful act. Pyrogallie acid was an ordinary article of commerce and had no relation at all to "arms, ammunition, gunpowder," or kindred matters. The proclamation purported to be made under section 43 of the Customs Consolidation Act, 1876, which provided that the "importation of arms, ammunition, gunpowder, or any other goods may be prohibited by proclamation." The Customs, to justify their action, must show that the expression "any other goods" in section 43 was not subject to the *ejusdem generis* rule of construction. The genus would include arms, ammunition, gunpowder, and any other things which would tend to the breach of the peace, or any engines of destruction and disturbance. If it had been intended that the expression "any other goods" should have the unlimited meaning contended for, the words "arms, ammunition, gunpowder," in the section, were mere surplusage. On the ordinary principles of construction, section 43 of the Act of 1876 was not a general section. It would be doing violence to the statute to construe it in a general sense. "Any other goods" must be limited to the class of goods named in the section. Therefore the seizure of the plaintiff's goods by the defendant was without any colour of right at all. The seizure was unjustifiable and the plaintiff was entitled to immediate redress.

The Attorney-General (Sir Gordon Hewart, K.C.), submitted that the proceedings were entirely misconceived. The action was started in the Chancery Division by a writ issued

on September 17. The plaintiff claimed a declaration that the defendant had no lawful authority to deal with the goods; a declaration that the proclamation under which the goods were seized was invalid: an injunction to restrain the defendant from acting in respect of the goods under the proclamation; and delivery of the goods. The plaintiff started the action notwithstanding that proceedings had already been started under section 207 of the Customs Consolidation Act, 1876, to condemn the goods. In such proceedings, every question that was raised by the plaintiff could be decided. The position was that the goods were seized and notice of seizure was duly given on August 29. A claim for the goods was duly made by the plaintiff on September 1, which would be decided in the proceedings under section 207 of the Act of 1876. Pending those proceedings it was impossible for the Commissioners of Customs to dispose of the goods unless the goods were perishable, which was not the case. The defendant was a junior Customs officer and the goods were not under his control, but were under the control of the Commissioners of Customs. So that any order made against the defendant would be nugatory. Moreover, there was no ground for an interim injunction to prevent somebody from detaining or dealing with the goods. The plaintiff asked for the delivery up of the goods. To grant such an application was unheard of in an interlocutory proceeding. His Lordship was asked to decide the issue of the action in an interlocutory proceeding. The construction of section 43 was not so simple as had been suggested. There was a point of substance and a point of very great importance. The matter came before a Court of three Judges, including Lord Chief Justice Chry, in Ireland, before the war, in May and June, 1914, in *Hunter v. Coleman*. In that case the argument proceeded on the basis that "any other goods" meant any other goods. Two of the Judges in that case went into the history of the law before the Act of 1876 was passed. There were reasons of an historical kind as to the meaning of the words "any other goods," and these would be fully explored when the action would be tried. The present proceedings were entirely misconceived and unnecessary. The application should be dismissed.

Mr. Justice Greer said that he did not think it was necessary to deliver a judgment. His Lordship was inclined to think that the plaintiff's construction of section 43 was the right one. But he regretted that it was not possible to decide the question finally on that application. It was not right to decide a question of such importance in an interlocutory proceeding. It was a question of grave importance to the plaintiff and to other traders. The application would be refused, but without any order with regard to costs.

Government Scrap Lead.

At Bow-street Police Court on Wednesday, before Mr. Graham Campbell, Albert Evan Whatcott, 29, general dealer, of Pyrland-road, Canonbury, was charged on remand with stealing 40 tons of scrap lead, valued at £1,291., the property of the Ministry of Munitions.

The defendant was formerly sub-director of a department in the Ministry of Munitions concerned with allocating scrap lead to firms engaged on Government contracts, printers and others, who had been granted priority certificates. It was alleged that shortly after the armistice he sent in a requisition, in the name of the Premier Metal Foundry, for 40 tons of scrap lead, and in his official capacity passed it as being in order. The whole consignment was delivered at an address in Holborn, and was sold by the defendant for about £1,300.

Mr. George Jewell, controller of a section of the Ministry of Munitions dealing in scrap metal, said that he resigned his position in October, 1918, and returned in December. The requisition for 40 tons of lead alleged to have been sent in by the defendant stated that the metal was required for the manufacture of printing leads. It was the defendant's duty to satisfy himself that requisitions were in order, in which event he had authority to allocate the quantity required without consulting any other official. He had no authority to allocate the lead ordered by the requisition in question. It was not true that at the time of the armistice the Ministry had an enormous surplus of lead which they did not know what to do with, but about that time a few allocations were made for commercial purposes without priority certificates being received.

Mr. John William Griffin, managing director of the Premier Printers Lead Company, Limited, having given evidence, the hearing was again adjourned.

CORRESPONDENCE.

*. We do not hold ourselves responsible for the opinions expressed by our correspondents.

THE DYESTUFFS LICENSING SYSTEM.

Sir,—I am instructed by my committee to forward you the enclosed copies of correspondence exchanged between the Board of Trade (Industries and Manufactures Department), and this Association.

The matter dealt with is one of vital interest to the trade, and you may therefore like to publish the correspondence in your valued paper.—Yours, etc.,

THE BRITISH CHEMICAL TRADE ASSOCIATION,

O. F. BLOMFIELD, Assistant Secretary.

London, E.C. 3, September 22, 1919.

[SELECTED COPIES.]

The Secretary,

The British Chemical Trade Association,

London, E.C. 3, August 8, 1919.

Sir,—With reference to your letter of July 29, regarding representation of your Association on the Dye Trade and Licensing Sub-Committee, I am directed by the Board of Trade to state that the constitution of the Committee was settled, after careful consideration, when the Government scheme for affording State assistance to the Dye Industry, outlined in White Paper Cd. 9194, was prepared; and they regret that in the circumstances it is impossible for them to add to the membership of the Committee in question.—Yours, etc.,

PERCY ASHLEY.

Board of Trade

(Industries and Manufactures Department),

Gwyder House, Whitehall,

London, S.W. 1.

Percy Ashley, Esq., C.B.,

Board of Trade,

Industries and Manufactures Department,

Gwyder House, Whitehall, S.W. 1, Aug. 22, 1919.

Sir,—I thank you for the interview accorded to our Mr. Bromfield on August 14.

It is understood that the following summarises your statement at the interview in question.

1. That no definite policy has yet been formulated by the Government as to the disposal of the German dyes which it is understood are being taken by this country on account of the indemnity, but that if any firm is appointed as sole distributing agents on behalf of the Government, such firm will not be allowed to sell to one firm and refuse supplies to another at their discretion. That the Government will take the opinion of various bodies before making any decision, and that this Association is invited to offer its assistance in the matter.

2. That as regards our application for representation on the Licensing Sub-Committee, manufacturers and consumers are already represented, but merchants are not; you consider the present Committee well balanced and adequate, but you invite this Association to submit a definite statement as to the points in the present scheme upon which we disagree, giving our reasons, together with any suggestions we wish to make, and also a statement as to why we consider merchants' interests should be represented on the Committee. Further, that any representations we may make would be submitted to the President of the Board of Trade, and would be carefully considered.

3. That you expressly point out that the Board of Trade does not decline to recognise this Association, but on the contrary this Association is recognised by the Government as representative of the merchanting interests.

To deal with the above points *seriatim*:—

We are glad to note that if a trading firm is appointed as sole distributing agents for the German dyes referred to, they will not be allowed to supply to one concern and refuse another at their discretion. We should like to be assured also that the Government will not instruct any such firm to deal with the dyes in question on anything but an open market basis. I would like to insert here certain general observations which have a bearing on this matter:—

The policy of this Association, from its inception, has been to foster and protect the trade and interests of the British manufacturer and the British consumer. At the same time we oppose the principle of granting special concessions to any particular manufacturer or consumer or any particular group of manufacturers or consumers. It is generally assumed

to be of the highest importance, particularly at the present juncture, that the export trade of the country should be fostered. Dyes are exported and re-exported partly in their original (or reduced) form, and partly as an item in the finished product of dyed or printed goods, etc.

It is estimated that between 50% and 60% of the dyes imported into this country before the war were re-exported in the form of finished goods.

The question of re-exportation of dyes in the original form has also to be considered. It is submitted that if a proportion of the German dyes which are allocated to this country can be sold for re-export at attractive prices, this re-exportation should be allowed, with a view to retaining the British merchants' connection abroad in the meantime, and eventually supplying such connections with British dyes which it is hoped will be on the market and available for export by the time the stocks of German dyes are exhausted.

A great deal of prejudice, and considerable opposition has arisen during the last five years to a class of so-called merchants who have sprung up, and either by speculation or re-handling goods, simply served to increase prices to the consumer. The Association is also opposed to this class, but it is submitted that the *bona-fide* and legitimate merchant is a useful factor, as by his special organisation and trade knowledge, he acts as a financier, a distributor and an exporter, more efficiently than is possible to a manufacturer. This point can be amplified and detailed statements of facts can be produced if desired, but you will probably be prepared to accept the hypothesis without further remark.

It is therefore submitted:—

That the German dyes in question should be sold on an absolutely open market, that is to say, that the firm who are willing to pay the best prices should receive the goods, whether such firms are consumers, merchants or exporters.

That the dyes should be put on the market in comparatively small lots, in order to give the small consumer an equal chance with the large and financially powerful organisations to secure supplies. We deprecate anything in the nature of favouritism or opportunity to "corner."

That the distribution should not be effected by any particular or individual firm, whether camouflaged by an official title or not. There is strong opposition to the so-called "Central Importing Agency" already established. The information which must necessarily accrue to any individual concern acting in such a capacity may be applied at a later date or indirectly for individual advantage. I would mention here that the Association has received various protests on this point, and quite apart from the merchants' point of view, it is submitted that the present system is frequently exceedingly unsatisfactory to the consumer. Many consumers are averse to letting the "Central Importing Agency" know exactly what dyes they are using, because naturally every manufacturer has some particular method of working, which he will not under any circumstances risk getting into the hands of possible competitors. It would be preferable for the distribution of the German dyes to be undertaken either by a Government Department with expert whole-time assistants on the trade and technical sides, or if this suggestion is unacceptable on the ground of expense or reluctance to increase the scope of official action, it is suggested that this Association, representing merchants generally, and not any individual, should undertake the distribution for the Government, possibly somewhat on the lines of the United Kingdom Oil and Oil-Seed Brokers' Association. Further, if this suggestion were in principle considered acceptable, I think it could be arranged for the Association to undertake the work on a basis of actual out-of-pocket expenses only, and a guarantee that such expenses should not exceed a certain specified percentage. (This Association, under its Memorandum and Articles of Association is expressly precluded from trading or making any profit).

We contend that the present Import Licensing Committee, and also the Licensing Sub-Committee, are ill-balanced and unsatisfactory for the following reasons:—

Manufacturing interests are not fairly represented. It is true that the Dye Manufacturers' Section of the Association of British Chemical Manufacturers is represented on the Committee, and therefore presumably had a voice in nominating the Licensing Sub-Committee, but the smaller and independent dye manufacturers are not really represented at all, in so far as even if they are members of the Association of British Chemical Manufacturers, they have, under the constitution of that Association, no real voice in its management, and are entirely controlled and outvoted by the larger subscriptions paid, e.g., by Messrs. British Dyes, Ltd., and

Messrs. Leviustains. The consumers' interests are not fairly represented simply by Messrs. Bradford Dyers Association, and the Calico Printers Association; because, it is submitted, these two organisations, though admittedly the two largest individual consumers in the country, do not take between them 50% of the national dye consumption. The merchant interests are not represented at all. The whole Committee is constituted to deal with a question of importing, and importing is the business of a merchant, not a consumer. The consumer, generally speaking, wants stuff delivered on his doorstep in comparatively small quantities, and usually locks his capital up in manufacturing interests and book debts, and only wants to pay for supplies of raw material on or after delivery. The function of the merchant is to buy in quantity and finance in the country of origin of the imported merchandise, to arrange rapid and economical transport, and to deliver the goods on arrival in smaller quantities to suit the consumer. Before the war at least 95% of the imports of dyes were made by merchants or agents.

It is recognised by the Board of Trade, and admitted in their White Paper No. Cd. 9194: that certain dyes which are required in this country are not manufactured here. Whilst recognising the importance of fostering home production, it is submitted that it is nationally and financially unsound to prevent the importation of raw material which is either unavailable here or which cannot be produced to compete within a reasonable margin with the price at which the product of an allied nation can be delivered here without any principle of dumping being involved. It is suggested that it is in principle unfair to govern the business of the importing merchant, who is at least equally involved with the consumer, through a Committee composed exclusively of representatives of firms whose interests lie (as far as manufacturers are concerned) in preventing imports as far as possible, or (as far as consumers represented are concerned) in hindering imports by outside and competitive firms. It is submitted that such Licensing Committee should be as widely represented as possible, and that all parties interested should be given an opportunity of submitting their point of view.

It is therefore again requested that this Association may be allowed to nominate a representative or representatives to the Dyestuff Licensing Sub-Committee.

Our objections to the present "Central Importing Agency" are outlined above, but these can be amplified if you so desire. Yours, etc.;

The British Chemical Trade Association,
S. J. C. Mason,
Secretary.

The Secretary,
The British Chemical Trade Association,
80, Fenchurch Street, E.C. 3.
August 28, 1919.

Sir,—I am directed by the Board of Trade to acknowledge the receipt of your letter of August 22, and to say that your representations with regard to the importation of dyestuffs into the United Kingdom will be borne in mind in connection with the arrangements for the distribution of any supplies of dyestuffs which may be obtained from Germany under the Peace Treaty.

I am, however, to add that, as already pointed out, the Board cannot see their way to increase the representation on the Licensing Sub-Committee of the Trade and Licensing Committee.—Yours, etc.,

A. W. FLUX.

Board of Trade,
Industries and Manufactures Department,
Gwyder House, Whitehall, London, S.W. 1.

CHEMISTS IN GOVERNMENT FACTORIES.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—I have read both "Muldoon's" and Morrison's letters, and can assure "Muldoon" that he has my sympathy. The answer to Morrison's question as to why Muldoon took such a low salary as £175, in spite of the fact that he was a steel-works chemist is perfectly obvious. A big proportion of the chemists employed by the Ministry were men who had joined the colours and gone to France. When the Ministry found that there was a shortage of chemists they recalled from the colours a large number of these chemists, and put them in Class W.

These men were, however, still to a large extent under the control of the War Office. And if they had left the Ministry would have had to rejoin the army immediately. From the above facts it will be seen that the Ministry had a tremendous pull on them as they were not in a position to bargain, and had to accept the salary which was offered them. This pull, I am sorry to say, the Ministry did not hesitate to use, and the salary offered commenced at £150. "Muldoon," having come from abroad, and having forfeited his position there, was in the predicament of also having to take what was offered him.

Morrison lays great stress on the fact that he was a member of a big trade union which was in a position to enforce to a large extent its demands. I may, however, point out to him that if the chemists had adopted the methods of some of these unions there would have been nothing for him and his fellow-unionists to do, as all the explosive and chemical works would have been more or less at a standstill. These methods I am pleased to say were not adopted.

Morrison makes two very wild statements:—(1) that he did not find leadburners' wages large; (2) that it takes quite as long to become a good plumber and leadburner as to become a good chemist. Now, I was chemist for a considerable time at a Government explosive factory, and while there found that leadburners, aged nineteen in some cases, were taking home £10. to £14. per week. This fact disproves the statement that wages were not large, and apparently at the same time disproves that it takes as long to become a good leadburner as to become a good chemist. I certainly cannot imagine a chemist of nineteen getting such a salary. Of course the above figures include overtime, but although I put in any amount of overtime, being a chemist I was paid nothing extra for it.

Regarding Morrison's remarks concerning the dress of chemists at Gretna, I simply consider these futile, and beside the point. I did not actually work at Gretna, but was in Carlisle for a time, and had many friends there amongst the Gretna chemists, and also knew quite a number of workpeople from Gretna. All the time I was there I heard, in the main, nothing but good spoken of the chemists by the workpeople I knew. I certainly think that Morrison had better say nothing at all about the snobbery of chemists. Your true tradesman trade-unionist is the finest snob of any, and one has only to watch the way they treat their labourers to see this. I have been in industrial work all my life and have noticed this repeatedly.

I sincerely trust that Morrison will get rid very speedily of his jaundiced and spiteful view of chemists, and at the same time will devote himself to correcting a few of his own little faults before indulging in silly and spiteful criticism of a body of men whom everyone acknowledges worked well during the war and at the same time were not overpaid for that work.—Yours, etc.,

WEST GORTON."

Wealdstone, Middlesex, Sept. 22, 1919.

FUSION OF CARBIDE COMPANIES.

A CIRCULAR has been issued to the shareholders of the Nitrogen Products and Carbide Company, Limited, and the Alby United Carbide Factories, Limited, which states:—"On August 10, 1918, a circular was issued regarding the amalgamation of the two companies, but owing to negotiations regarding certain conditions proposed by the Norwegian Government, which were not quite clear or acceptable in the form put forward, the directors were unable to recommend that the amalgamation should then be proceeded with. The directors are pleased to say that the Norwegian Government have met them in a friendly spirit, which has resulted in the ambiguity of the wording being removed, and satisfactory modification of the terms to which objection was taken. The legal formalities on this side are now being completed, and the necessary notices of the meetings, together with the report and accounts, will be issued about the middle of next month."

FATALITY AT A CELLULOSE FACTORY.—An accident occurred at the British Cellulose Works, Spondon, Derby, on Tuesday, resulting in the death of William Deudeney and serious injury to Mr. Walton, chemist to the company. Certain plant which was being dismantled was being examined, and four persons were engaged on the work, but the accident occurred whilst the plant was out of operation.

THE GERMAN CHEMICAL ASSOCIATION AND INTERNAL ECONOMY.

THE Association for the Protection of the Interests of the Chemical Industry in Germany recently took the initiative in convening a meeting in Berlin, which was attended by representatives of industries from all parts of the country, to discuss questions of internal economic policy, and particularly the fluctuating attitude hitherto assumed by the Government in these matters. Although not specifically mentioned, it is obvious that the industries are opposed to the substitution of works' councils for the existing works' communities, which were brought into operation as a temporary expedient at the end of last year for the purpose of giving the workmen on these communities, one of which is established at each works, a voice in the decision of labour and other questions affecting their interests. On the other hand the later scheme contemplates a grant to the workmen's representatives not only of a voice, but also to confer upon them a vote in determining labour questions and other far-reaching powers, including the position of directors, the right of inspection of books, and balance sheets, etc.

The meeting, evidently having in mind the considerations set forth, adopted a series of resolutions. In the first place it was decided that the serious necessities of the near future can only be surmounted by the establishment of a sincere solidarity between producers and a confident co-operation between employers and workmen. As a consequence the meeting welcomed the fact that such a combination for the chemical industry has already been provided by the creation of the "Imperial" community for chemistry; and it was declared to be necessary for the self-governing bodies formed by the works communities with the addition of representatives of merchants and consumers to be maintained without further delay. In order to provide a legal basis for these organisations independent of changes in Government departments, the meeting resolved to submit the following demands to the Government: (1) official recognition of the works' communities and the self-governing bodies formed by them; (2) the immediate constitution of the Imperial Economic Board which, in the opinion of the meeting, must be given a previous hearing in connection with every proposed regulation of economic questions by the National Assembly, and be able on own initiative to submit proposals of their own; (3) the works' communities to be consulted on all economic, and social, and political problems before they are decided, until these demands have been fulfilled; and (4), the self-governing bodies to have transferred to them the exclusive right of sanctioning imports and exports.

The Chemical Association, by adopting the above resolutions, has allied itself with the ideas and demands of a fundamental nature, such as were embodied with emphasis in the recent appeal published by the National Party. The Chambers of Commerce and manufacturers in general, also regard with feelings of alarm the proposal to replace the works' communities by works' councils having such extended powers as to threaten to imperil the future interests of German industries.

EXPORT OF COAL-TAR PRODUCTS.

THE Board of Trade (Export Licence Department) draw attention to the fact that the export of coal tar and derivatives thereof (except solvent naphtha, cresylic acid, and mixtures containing cresylic acid) suitable for use in the manufacture of dyes and explosives, whether obtained from coal tar or other sources, and mixtures and preparations containing such products or derivatives, is still prohibited to all destinations. Certain coal-tar products, such as naphthalene and its derivatives, toluol and its derivatives, picric acid, xylol and its derivatives, carboic acid crystals, anthracene oil, benzole and its derivatives, cresols (ortho, para, and meta) and their derivatives, were originally mentioned by name in the British list of prohibited exports, but these prohibitions have now been merged in the inclusive prohibition on the export of coal-tar products. The export of naphthalene, toluol, picric acid, and the other coal-tar products above mentioned, should therefore be regarded as prohibited to all destinations, and applications for licences to export them should be addressed in the usual way to the Controller, Export Licence Department, 1, Queen Anne's Gate Buildings, Westminster, S.W. 1.

BRITISH CHEMICAL STANDARDS.

THE Superintendent of Research, Royal Arsenal, Woolwich, who is now co-operating in the standardising of steels, has had a number of standard steels tested in the Government Research Laboratory at Woolwich, and has supplied the results given below, which have been issued by Messrs. Ridsdale and Co., Middlesbrough, under the auspices of the body of co-operating analysts. They are, of course, not included in the general averages shown when the standards were issued, but will serve in conjunction with them as a guide for firms doing work for the War Office and others. The Superintendent wishes it to be made clear that the homogeneity of the bulk of standardised turnings represented is not in any way guaranteed by the War Office. The homogeneity has, of course, been fully verified by the firms who provided the bars and by Messrs. Ridsdale and Co.

ELECTROLYTIC FLUORINE.

A PROCESS for the preparation of fluorine has been worked out by Messrs. Argo, Mathers, Humiston, and Anderson, of the Research Department of the United States Chemical Warfare Service. The usual method is that of Moissan and Lebeau—electrolysis of anhydrous hydrofluoric acid HF, to which some potassium fluoride KF is added to make the liquid a conductor of electricity. The vessel should be of platinum; copper may be used, as was found later, but the electrodes must be of platinum or platinum-iridium. Acheson graphite is attacked; the cell must artificially be cooled. The hydrofluoric acid may be made in lead vessels, but it takes up lead then, and is hence unsuitable for analytical purposes. The HF is sometimes prepared by heating the compound HF KF, which is more easy to deal with than the viscous acid. Argo and his collaborators electrolyse this fused compound instead of its solution in hydrofluoric acid. The HF KF fuses at about 200° C. The fusion is accompanied by a slight decomposition, and as the salt is never quite free of water, the first gas evolved during the electrolysis is impure. The electrolysis is conducted in a heavy copper cylinder, about which is wound a nichrome coil. The copper is slightly attacked by the bath. The copper is the cathode; the anode is a rod of graphite, which is surrounded by a diaphragm, the space between the carbon and the diaphragm being packed with pure powdered fluorspar CaF_2 . The KF becomes concentrated in the bath, and when the liquid has turned too viscous, in spite of the addition of more HF, the cell contents are poured out into a copper basin, in which the KF solidifies. The electrolysis evolves heat, and with too high current density there may be sparking and considerable heat evolution in the cell. In fact, the external heating seems unnecessary, and the process does not seem to give much satisfaction, since modifications are suggested. The use of NaF instead of KF seems advisable. But fluorine is, under ordinary conditions, probably the most active element known, as it inflames coal gas, charcoal, and sulphur instantaneously, and attacks almost any element. According to the new experiments, however, pure fluorine is not poisonous, and not so irritating to the lungs as generally believed, and is, in fact, less so than chlorine.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Sulphate of Ammonia.—Fair business for the period appears to be doing in sulphate of ammonia, and the new prices are generally recognised as just and equitable. There are buyers waiting, of course, to whom the current figure seems dear, but they will have no option but to come along later on. Not very much is moving in the export line, but a little trade takes place at about £25. per ton, f.o.b. This market is now pretty well controlled in one way or another, and there is not much freedom.

Basic Slag.—This is in excellent request, and looks like going into consumption now more than ever before. Certainly, the material is regularly rising in popular favour. Professor Somerville, in an address as president of the Agricultural Section of the British Association, specially recommended the use of basic slag on poor pastures, and summed up as follows: Few forms of agricultural expenditure are more certain in their results than the judicious use of manures on grass land. The meat and milk producing capacity of the country can be largely and rapidly increased, with great pecuniary gain to the farmer, and still greater economic advantage to the nation. Poor clay soils can be rapidly and profitably improved by the use of phosphates, especially basic slag.

Superphosphates.—Here, also, there is a fair demand, with makers indisposed to undertake business for delivery much ahead. Supplies of raw material and increasing manufacturing and labour costs are playing a very important part in this section of production as in most others, and the superphosphate makers in particular do not regard the future as being at all clear.

Bones and Bone Meals.—Supplies of imported stuff are still very small. With regard to bones, £12. has been paid for mixed crushed from Egypt, but these sales have been of limited character. In bone meal itself there is little change, but a moderate demand of late has ranged up to £14., and even £15., for the better grades. Meat and fish meal sell well where offered at values round about 27s. 6d. and 30s. per unit for ammonia and 2s. 6d. for phosphate.

Blood and Tankage.—Scarcity of freight room continues to prevent arrivals of these fertilising materials reaching this country to any extent, and supplies are still well on the short side. Tankage has been priced recently at 27s. 6d. per unit of ammonia, with 2s. 6d. for phosphates, whilst dried blood is reported to have been in good inquiry at 30s. to 32s. 6d. per unit.

Other Fertilisers.—There appears to be very little, if any, calcium cyanamide on offer in this country, and nitrolim for November delivery is said in one quarter to be likely to cost up to £25. per ton. The American Cyanamid Company has apparently been working to entire capacity, and has attained new records in production. It has recently acquired membership in the Florida Pebble Phosphate Export Association, organised by the leading pebble phosphate mining companies for the promotion of foreign trade, and regards the outlook as promising for a profitable export business in phosphate rock during the next two years.

Interesting Continental Fertiliser Group.—It is reported that the Phosphates Tunisiens have, along with the Montecatini Company, acquired control of the Colla Concimi (Glue and Fertiliser Company) of Rome; and a combination of this latter company with the Unione Concimi, which is related to the same group, appears to be another probability. It is to be noted that the Colla Concimi and the Unione Concimi are the two most important fertiliser producing concerns in Italy, and that the Montecatini can furnish them with the necessary sulphuric acid, whilst the Phosphates Tunisiens will provide, on the other hand, what is required in crude phosphates.

Alsatian Potash.—It is held in certain quarters that it would be to the interest of the Alsatian concerns to adhere to the German Potash Syndicate instead of competing with it. This is not the opinion held by those interested in Alsatian potash. When the Alsatian mines were under the control of the German Syndicate their output was limited to the lowest possible figures; now the Alsatian mines are producing 3.750 tons of low- and high-grade potash salts daily, and this quantity will soon be considerably increased. Contrary to what is asserted by the German Syndicate, that the Alsatian and German potash salts are identical, the former product is of a decidedly richer quality. The raw salts produced by the German mines are carnallite containing 9-12% K_2O , and kainit containing 12-15% K_2O ; while the Alsatian mines can

offer sylvinites 14% (French kainit), with the potash content of 14-16% K_2O , and sylvinites 20%, with a content of 20-22% K_2O . Considerable quantities of 80-98% potash are also being produced at the potash mines in Alsace.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

The production of tinplates is satisfactory, and the mills are increasing their outputs—with the exception of those situated in the Llanelly district where there is a water famine, and some 6,000 men are out of employment. As stated in these notes last week, the experiment of using sea-water in the works has been thoroughly tried and has been a success as regards the "white" and the "finishing" but not for the "black" process. Some of the operatives in the Neath area have had an unofficial meeting, when it was decided to notify the employers that unless all the employees engaged in the trade are allowed to benefit under the recent 12½ per cent. award, they would cease work to-day (Saturday). This has caused some anxiety, but as it is unofficial and not authorised by the men's union it is not likely to meet with general support.

Negotiations are proceeding for the acquisition by a large firm of soap manufacturers of the extensive war works in the Pembrey Burrows. These works were put up under Munitions authority for the manufacture of explosives, and employed during the war some 7,000 people. They are of vast extent, situated in healthy surroundings, and could easily be adapted for the making of margarine and soap.

The Cae Coch mines in Snowdonia which were developed during the war for the purpose of providing sulphur pyrites for the Ministry of Munitions are likely to be closed, and the plant and machinery installed therein during the last few years are intended for sale.

The Basic Fertilisers, Ltd., is the name of a new company who intend to manufacture and deal in raw basic slag, and all kinds of chemical fertilisers. The capital is £30,000, in £1. shares. The company, which is a private one, has for its first directors, Mr. H. G. K. Palmer, shipper, The Hall, Johnston, and Mr. G. Jones, chemical manure manufacturer, Southernwood, Newport.

The patent fuel industry is very active, and all kinds of makes are being quickly bought up, the demand, especially the foreign portion, being of an urgent kind. All the works are operating to their fullest extent, and outputs are on the increase. Important cargoes left Swansea during the week for St. Nazaire, Bordeaux, St. Brieux, Casa Blanca, Palermo, Venice and Dieppe. The supply of pitch is not so good, and prices are advancing.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

The ironfounders' strike has already adversely affected the Cumberland and North Lancashire hematite pig-iron trade, business in the iron market being practically idle, and if, as seems probable, users are unable to take deliveries, and more furnaces are damped down, it is certain that the coking industry will be hard hit. Even now all the 380 by-product ovens in East Cumberland are diminishing their operations. They were working only at two-thirds of their capacity a few weeks ago. Within the last few days, however, one or two batteries have further decreased their production, and even then difficulty is being experienced in getting rid of the entire output. In any event, some apprehension is felt as to the maintenance of the rail mills at Workington and Barrow in operation. They are working merely from hand to mouth, and unless Continental and Colonial orders can be secured, it is evident that there must be a considerable decrease in the production of ordinary iron. In that case, of course, the requirements of local coke will undergo a further shrinkage. East Coast coke supplies to the district are still unaffected, no furnaces on low phosphorus brands of iron having damped down, and to East Cumberland this week they are 8,000 tons and to the Furness district, 14,000 tons. The make of by-products is naturally smaller. There continues to be a keen demand for benzole and for sulphate of ammonia, the output in each case being fully absorbed, and pitch also is moving away freely. Creosote is rather duller.

REPORTS OF COMPANIES.

Magadi Soda Company, Limited.

The eighth ordinary general meeting was held in London on Monday, Mr. Samuel Samuel, M.P., D.L. (chairman of the company), presiding.

The Chairman, in the course of his speech, said: On the face of the accounts it would appear that there has been a trading loss of £48,954., but this is not the actual condition. A large proportion was expended on labour, which will not recur. The sales which the company made were, unfortunately, much smaller than we had anticipated. The loan at the end of the year had increased from £50,000. to £112,000., this amount being advanced by various shareholders pending the increase of capital which the directors had already announced to the shareholders would be necessary to complete our facilities for carrying on the business on a sound commercial basis. I should like to call your attention to the very serious labour troubles that occurred in East Africa just when we were ready to start production. Owing to the war, it was impossible to get the necessary machinery completed to carry out the plans of the company to eliminate as far as possible manual labour and to introduce mechanical appliances in every stage of our operations. We were compelled to pay about three times the amount for labour that we had ever done before, and in addition to this we had the greatest difficulty in securing the necessary men to carry on, and we have had to-day very reluctantly virtually to shut down production by hand labour in order not to waste money, and patiently await the arrival and erection of the machinery to continue our operations on a profitable basis. The stock in hand on December 31 last amounted to £53,175., as against £10,965. for the year before. This stock would all have been disposed of at a remunerative price had the war conditions continued. But in consequence of the armistice and the release of the soda ash, the buyers preferred to pay a higher price to taking the new article, especially in view of the fact that the purity of our practically raw soda is so fine that the authorities insist upon levying a higher duty for our raw soda, especially in India, Japan, etc., than they levy upon the soda ash, which is a manufactured article, whilst ours can be designated "raw" material. When we are producing the soda ash by further processes which are necessary, you will be surprised to hear that we shall be able to enter the markets of India and other places at a lower rate of duty. The incident just mentioned was a very great disappointment to your directors, but when one has to deal with Government officials it is certainly impossible to understand their frame of mind or the principles that underlie their decisions.

Last year I put before the shareholders that our claim against the Government for the use of our railway and water supply was still outstanding, but that we were in hopes of being treated fairly—we never expected generosity—from the Treasury, who, although allowing lavish extravagance in all departments, are more than niggardly when the interests of individuals or companies like ourselves are concerned. We have received a letter from the War Office repudiating all liability, and pointing out that under the terms of our agreement with the Colonial Office the Government had the right to use our railway and water supply. We admit that even had they not the right to use them we should have placed the whole of our resources and facilities at the disposal of the nation; but, in taking the position they do, they omit the essential condition that if they commandeer property they must pay a reasonable compensation for using it, and there is nothing whatever in the agreement to say that the Government can take over our property without a reasonable compensation for the disturbance of our trade. We shall, therefore, continue to press our claim. Our Irlam works have been commandeered and our machinery removed. In this case the Government have paid us for the actual machinery they have seized, but they have taken possession of our property at Irlam, which they are using for military purposes, and although we have sent in our claim for rent, we have received nothing up to the present either in the way of rent or compensation.

We have discontinued the production of soda by manual labour owing to the enormous increase in the cost, and we are doing everything we can to expedite the delivery and shipment of the necessary material so as to convert the whole operations to a mechanical production, and reduce the employment of labour to a minimum. We are satisfied that we shall have an organisation capable of handling very large quantities at a minimum of cost. We are also satisfied from the experi-

ments that have been made by our chemists that the article we shall produce will be equal, if not superior, to any that is in the market. We must frankly tell you that we do not see any prospect of producing soda ash during the current year of 1919, but we venture to believe that, unless we are disappointed by labour troubles in this country or other unforeseen circumstances, we shall have the whole of our works completed and producing by the spring of next year. We have had so many disappointments that we do not want to be too sanguine at the present time. The fresh capital which we asked the shareholders to provide us with was readily supplied. We have entered into certain contracts in various markets, which we believe will at least give us a sufficient trade to pay our expenses. We shall be able to sell our soda ash and other products at a price that will defy competition so soon as all our mechanical appliances are in working order, and we are therefore satisfied that the contracts we have made will give satisfactory results to our buyers against no matter what competition they are faced with, as well as to our company. We, of course, shall have in the immediate future to wait patiently for the completion of our works, having decided to stop everything else until this most essential condition has been reached. The Chairman concluded by moving the adoption of the report and accounts.

Mr. H. F. Marriott seconded the resolution.

The Chairman, in reply to questions, said that the labour trouble with which they had had to contend was merely a passing difficulty. The directors had no intention of reducing the capital by cutting down the ordinary shares.

The resolution was unanimously agreed to.

Eastern Chemical Company, Ltd.

The report for the year ended March 31 states that the net profit, after writing off £7,177. for depreciation, is £13,843., as against £14,245. for the previous year. By adding to the above £13,843. the net sum brought forward from previous year—namely, £7,877.—a total of £21,720. is arrived at. Out of this the directors recommend the payment of a dividend of 10 per cent. on the ordinary shares, less tax at 6s. in the £., which will absorb £5,089, and leave a credit balance to carry forward of £16,631. from which to meet liability for English tax and excess profits duty. The terms of Treasury sanction for the issue of 26,305 ordinary shares, referred to in the last annual report, dated December 10, 1918, have since been amended, and these shares have been offered to the shareholders at 30s. in London, or Rs.18 in Bombay. The issue has been considerably over-subscribed, and the new shares are being allotted to the shareholders in accordance with the terms of the offer. The premium that will be obtained from this issue, added to the sum carried forward from profit and loss account, will, the directors hope, be sufficient, after meeting the liability for taxation already referred to, to enable them in due course to submit to the shareholders a scheme for the conversion of the deferred shares into ordinary shares on the basis of two of the latter for one of the former. The gross profits for the past year were slightly less than those for the previous year owing to the increase in cost of raw materials and packages, but the difference was more than made up by a reduction in general expenses. On the other hand, a larger amount was written off for depreciation, with the result that the net profit is reduced by £402. The turnover for the year 1918-19 was well maintained up to the time of the armistice, when, owing to the effects of a cessation of hostilities, combined with famine in India, there was a slight drop in the volume of sales, but at the close of the financial year the position had improved, and the total turnover was appreciably in excess of that of the year 1917-18. The plant has been maintained in good repair, and the efficiency of various processes enhanced, thereby effecting reductions in costs of manufacture. During the general strike of mill hands in January there was some slight interruption in manufacture at the company's works caused by intimidation of the workers, but this was quite temporary, and no further trouble has been experienced.

Associated Portland Cement Manufacturers (1900), Ltd.

At a meeting of the board, on Monday, the directors resolved to recommend the payment of 2½ years' dividend, less tax, on the five-and-a-half per cent. cumulative preference shares for the period from January 1, 1917, to June 30, 1919, after providing £161,478. for depreciation, reserves, and sinking funds, thus clearing off all arrears. The amount carried forward at June 30 was £125,678., as compared with £190,228. at June 30, 1918.

CHANCE ^{AND} HUNT, LIMITED.

Buxton Lime Firms Company, Ltd.

A falling-off of about £4,200. in the net profit is revealed by the report, the gain for the past year being £33,430., as compared with £37,677. a year ago and £28,719. for 1916-17. It should be explained, however, that the profit on this occasion has been arrived at after providing for debenture interest and writing off £20,649., whereas last year the amount written off was only £16,965, a difference of £3,684. A further dividend of 2½ per cent. is proposed, making, with the interim distribution, 5½ per cent. for the year, which will leave £24,132. to be carried forward, as against £15,251. brought in. Last year the dividend was 6 per cent., with a bonus of 2 per cent., and for 1916-17 it was 5½ per cent.

Campania de Salitres de Antofagasta.

For 1918 net profits amount to 22,305,520dols. Dividends amounting to 11,520,000dols. have been paid, and transferred to the oficinas fund 8,000,000dols., and to the contingencies exploitation fund 2,000,000dols., to the amortisation of fund 785,520dols.

British Portland Cement Manufacturers, Ltd.

At the annual meeting on Friday of last week, a resolution splitting the £10. preference shares into 10 £1. shares was carried unanimously. The preference share dividend and a dividend at the rate of 8 per cent. per annum on the ordinary shares were declared.

Elliott's Metal Company, Ltd.

The report for the year ended July 31 last states that, after paying debenture interest and providing for excess profit duty, there remains a profit of £64,051., to which must be added £92,953. The stock of copper has been valued on the same basis as last year. The building, plant, and machinery added £28,902., being the balance standing to the credit of profit-and-loss account, after paying excess profit duty up to July 31, 1918, making a total of £92,953., which the directors propose to appropriate as under: To pay a dividend at the rate of 5 per cent. per annum on the preference shares (of which an interim dividend amounting to £3,382. has already been paid), £6,765.; to pay a dividend at the rate of 3s. per share on the ordinary shares, subject to income tax (of which an interim dividend amounting to £14,105. has already been paid), £42,317.; to place to reserve fund (making a total of £110,000.), £20,000.; to write off expenses of new capital (stamp duty), £2,500.; to carry forward £21,371.; at Selly Oak have been fully maintained, as heretofore, out of revenue. In accordance with the special resolutions passed at the meetings held on May 15 and June 3 last, the revised memorandum has been submitted to the Courts, and the alterations were sanctioned on July 22. The increase of £1,000,000. in the capital of the company, passed at the same meetings, has been duly registered and stamp duty paid.

Odum's Nitro-Phosphate and Chemical Company, Ltd.

The balance-sheet for the year ended June 30, shows, after allowing £9,000. for excess profits duty, and including the sum of £1,488. 12s. 11d. brought forward, a balance standing to the credit of profit and loss account of £13,034. 15s. 0d. The directors propose to place to reserve £1,500., and to pay a dividend of 15%, £6,750., leaving to be carried forward £4,784. 15s. 0d. An increased supply of labour and raw material has enabled the company to do a larger trade with satisfactory results. There is a possibility of a shortage of raw materials during the coming season.

COMING EVENTS.

Society of Chemical Industry, Manchester Section.—First meeting of the new session at the Grand Hotel, Friday, October 3, at 7 p.m. Chairman's address: "Some Notes on the Rhineland Chemical Works," by Mr. John Allan.

Oil and Colour Chemists' Association.—The first meeting of the 1919-20 session will be held on Thursday, October 9, at the Food Reform Club, 2, Fumival Street, London, E.C., at 7 p.m. Two papers will be given by Mr. A. de Wade entitled (a) "Notes on the Permeability of Paints and Varnishes," (b) "A Suggested Method for Calculating the Costs of Ready-Mixed Paints." Chemists who are interested in these questions are invited to apply for tickets of admission to Mr. H. H. Morgan, Collingbourne, Hounslow.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W., 1., whence further information may be obtained:—

Canada.

A firm of manufacturers' agents at Toronto are desirous of obtaining agencies on a commission basis for British manufacturers of dyes. The territory to be covered consists of the whole of Canada. (Reference No. 638.)

New Zealand.

A firm of commercial brokers and merchants in Auckland desire to get into touch with United Kingdom manufacturers of veneers, asbestos sheets, white lead, paint, linseed oil, etc., with a view to representing them as agents in the Dominion. (Reference No. 645.)

Belgium.

A Belgian inquirer in Brussels desires agency for British firms exporting drugs, etc. (Reference No. 653.)

Italy.

An agent, of many years' standing in Turin (A French subject), desires to obtain agencies for United Kingdom manufacturers and exporters of chemical products. (Reference No. 660.)

A general agent and importer in Milan desires to obtain agencies exclusively for Italy for United Kingdom manufacturers of paints and varnishes, and chemical and pharmaceutical products. (Reference No. 661.)

Scandinavia, Finland, Russia, etc.

A Copenhagen firm desire to obtain the sole representation of United Kingdom exporters or manufacturers of greases and oils (lubricating, burning, benzine, benzol, etc.), for Scandinavia, Finland, Russia, and Germany, if desired. (Reference No. 663.)

Argentine Republic.

H.M. Commercial Secretary of Legation at Buenos Aires reports that a firm in that city, who already represent a number of important British firms for the sale of various classes of goods, is desirous of obtaining the representation of a United Kingdom manufacturer for each of the following lines: Chemical products for pharmaceutical uses, and industrial chemicals. (Reference No. 670.)

A British subject, with twenty years' experience in South America (sixteen in Argentina), is desirous of obtaining agencies for United Kingdom manufacturers and exporters of paints and varnishes, and particularly manufacturers' specialities in these or other lines. (Reference No. 671.)

Brazil.

A general commission agent, British, established at Rio de Janeiro since 1888, would be glad to act as sole agent for an exporter of heavy chemicals. (Reference No. 672.)

Estonia.

The following list of goods urgently required in Estonia has been received from the Estonian Provisional Legation: Petroleum, naphtha, engine oil, cylinder oil, kolophonium, quebracho, caustic soda, glue, and fertilisers. Further particulars may be obtained by United Kingdom firms interested from the Estonian Minister, Estonian Provisional Legation, 45, Markham Square, London, S.W. 3.

Roumania.

A bank in Bucharest wishes to be put in touch with United Kingdom manufacturers and exporters of pharmaceutical and chemical products. (Reference No. 577.)

Chili.

A representative of a hat factory in Santiago, expected to arrive in England shortly, is desirous of getting into touch with aniline dye producers. He will also be interested in the purchase of dyes for hat manufacture. (Reference No. 587.)

Czecho-Slovakia.

Two reliable merchants wish to act as agents for British firms dealing in chemicals and colours. (Reference No. 656.)

H.M. representative at Prague reports that he has received many applications from different parts of Czecho-Slovakia for catalogues and price-lists of chemicals.

British firms who are interested in these goods should send catalogues direct to the Chambers of Commerce in the important centres in Czecho-Slovakia, addressed as follows: Obchodni a zivnostenska komora (Chamber of Commerce), vyvozní kancelar (Export Department), at Prague, Budweis, Olomouc, Brno, Opava, Eger, Reichenberg, Plzen, Bradeč-Kralove, Bratislava, Kosice, or Troppau in Silesia.

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS.

DENSITY AND TEMPERATURE.

MEMBERS of organic compounds belonging to homologous series, differing in composition by the group CH_2 (for instance, the hydrocarbons methane CH_4 , ethane C_2H_6 , propane C_3H_8 , etc., and similarly the alcohols, acids, ethers, etc., derived from the hydrocarbons) show many striking regularities in their properties. Melting and boiling points rise with increasing molecular weight; solubility, refractive power, and activity grow or diminish, and so on. These regularities extend to the molecular volumes, but there is no similar relation for the densities. As a rule, the density diminishes as the molecular weight increases. Thus the densities of benzene C_6H_6 , toluene C_7H_8 , xylene C_8H_{10} are 0.8790, 0.8707, 0.8637, and for methyl acetate, propionate, and butyrate the figures are 0.9593, 0.9383, 0.9207. But in the case of the hydrocarbons pentane, heptane, octane, the density increases with the molecular weight—viz., 0.6454, 0.6705, 0.7005,—whilst in the case of the alcohols, methyl, ethyl, and propyl, there is no regularity at all, the densities being 0.81, 0.8065, 0.8183. The figures given refer to the temperature of 0°C . W. Herz, of Breslau, who is studying the correlation of properties, points out in the *Zeit. für Elektrochemie*, however, that at high temperatures, near the critical points of the respective compounds, there is a regular increase of the density with increasing molecular weight, as one would be inclined to expect, and that the ratio of the densities of two members of a homologous series increases regularly with increasing temperature. At 240°C . the alcohols, methyl, ethyl, propyl, e.g., the critical temperatures of which are 240° , 243° , 263.7°C ., have the densities 0.2722, 0.3825, 0.4920, and this regularity is very general, but does not hold for solids, of course.

DENSITY AND TEMPERATURE.

MEMBERS of organic compounds belonging to homologous series, differing in composition by the group CH_2 (for instance, the hydrocarbons methane CH_4 , ethane C_2H_6 , propane C_3H_8 , etc., and similarly the alcohols, acids, ethers, etc., derived from the hydrocarbons) show many striking regularities in their properties. Melting and boiling points rise with increasing molecular weight; solubility, refractive power, and activity grow or diminish, and so on. These regularities extend to the molecular volumes, but there is no similar relation for the densities. As a rule, the density diminishes as the molecular weight increases. Thus the densities of benzene C_6H_6 , toluene C_7H_8 , xylene C_8H_{10} are 0.8790, 0.8707, 0.8637, and for methyl acetate, propionate, and butyrate the figures are 0.9593, 0.9383, 0.9207. But in the case of the hydrocarbons pentane, heptane, octane, the density increases with the molecular weight—viz., 0.6454, 0.6705, 0.7005,—whilst in the case of the alcohols, methyl, ethyl, and propyl, there is no regularity at all, the densities being 0.81, 0.8065, 0.8183. The figures given refer to the temperature of 0°C . W. At 240°C . the alcohols, methyl, ethyl, propyl, e.g., the critical temperatures of which are 240° , 243° , 263.7°C ., have the densities 0.2722, 0.3825, 0.4920, and this regularity is very general, but does not hold for solids, of course.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

The specifications of the following applications are not printed by the Patent Office until the complete specifications have been accepted.

September 15th to 20th (continued)

- Acid Process for Production of White Lead. Arrowmath, H. T. 22,825 and 22,826.
- Anhydrous Magnesium Chloride and Anhydrous Calcium Chloride. Ashcroft, E. A. 23,000.
- Manufacture of Oxides or Salts of Tungsten, or of Metallic Tungsten. Ashcroft, E. A. 23,001.
- Manufacture of Compounds of Metals, or of Metals, or Non-metals Themselves from Ores, Minerals, Intermediate Products, Residues, Wastes, etc. Ashcroft, E. A. 23,002.
- Manufacture of Aluminium, or Its Oxides or Salts. Ashcroft, E. A. 23,003.
- Explosives. Bernardini, L.; and Manuelli, C. 22,775.
- Purification of Gas. Burgoyne, J. S.; and Holt, C. E. 23,167.
- Cyanide and Cyanogen Compounds. Calvert, G. 23,211.
- Treatment of Sulphide Minerals. Capron, F.; and Petersson, E. 23,128.
- Manufacture of Alcohol or Ether. Damiens, A. A. L. J.; Loisy, M. C. J. E. de; and Piette, O. J. G. 22,739.
- Treatment of Peat. Densified Peat, Fuel, and Products, Ltd.; and Macdonald, D. B. 23,178.
- Cleaning, Scouring, and Polishing Powders or Pastes. Denton, G. R. 22,876.
- Ascertaining Specific Gravity. Evans, H. G. 22,603.
- Derivatives of Bromoacetylated Urea Compounds. Farbenfabriken vorm. F. Bayer and Co. 22,766.
- Trimethylacetyl Salicylic Acid and Its Homologues. Farbenfabriken vorm. F. Bayer and Co. 22,767.
- Manufacture of Precipitate Rich in Alkalies and Used in Ash from Raw Juices and Waste Liquors of Sugar Factories. Kowalski, M. von Wierusz-. 22,774.
- Centrifugal Separation. Mauss, W. 23,206.
- Treating or Saturating Amido Organic Substances to Form Salts. Morris, H. N.; and Morris and Co., H. N. 22,940.
- Extracting and Concentrating Aromatic, Flavouring, or Colouring Matters, etc. Peek, Fream, and Co.; and Whymper, R. 23,022.
- Gasification of Solid Fuel. Rincker, F. G. C. 22,785.
- Recovery of Metals from Slags. Vautin, C. 22,651.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 6d. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane. W.C.

1917.

- Superphosphates. Chemische Fabrik Melle Akt.-Ges.; and Rohsmat, O. 3,509. 104,693
- Acetaldehyde. Deutsche Gold- und Silber-Schiedeanstalt vorm. Roessler. 8,486 and 8,565. 107,584 and 107,585

1918.

- Recovery of Gold, Silver, and Radium from Extremely Dilute Solutions, particularly Seawater. Baur, E.; and Nagel, O. 5,104. 114,316
- Compositions Having a Basis of Cellulose Acetate. Dreyfus, H. 7,192. 132,283
- Centrifugal Separators. Brownlow, R. S. 9,555. 132,291
- Aspirin (Acetyl-Salicylic Acid) Tablets. Pickard, J. A.; Rankin, I. G.; and Pickard, Ives, and Rankin. 9,684. 132,294
- Continuous Sulphonation of Aromatic Hydrocarbons other than Benzene. Barbet et Fils et Cie. E. 10,117. 132,298
- Distilling Hydrocarbons or Converting Them into Products of Lower Boiling-points. Clark, L. 14,658. 132,201
- Coke Ovens. Piette, O. 14,725. 132,201
- Dyeing, Staining, and Mordanting by Means of Salts of Titanium and Iron. Barnes, J.; Wrigley, H.; and Spence and Sons, P. 14,740. 132,345
- Bismuth Compounds and Metallic Bismuth Free from Arsenic. Busvold, N. 15,862. 132,659
- Sulphur Dioxide. Grayson, J. 17,813. 132,387
- New Colouring Matters. A'Brassard and Crawford, F.; and Singer, A. 18,016. 132,390
- Aluminium Alloys. Wigan, O. S.; and G'lover, W. 20,292. 132,411

1919.

- Benzoic Acid. Leach, F. P.; and United Alkali Co. 2,943. 132,433

COMPLETE SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

1919.

- Hydrocarbon Liquids from Carbon. Rousseau, F. P. A. 14,086. 132,490
- Fertilisers Containing Nitrogen and Phosphoric Acid. Norsk Hydro-Elektrisk Kvaeldesfabrik. 15,536. 132,496
- Liquid Ammonia. Norsk Hydro-Elektrisk Kvaeldesfabrik. 15,536. 132,504
- Recovering Ammonium-aluminium Sulphate from Aluminium Sulphate Solutions Containing Ferric Oxide. Gans, R. 22,079. 132,510
- Soap. Gans, R. 22,080. 132,511
- Preparing Acetic Acid from Acetylene as the Primary Material. Soc. des Acieries et Forges de Firminy. 22,482. 132,529

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Vulcanising India-rubber. S. J. Peachey, Davenport, Stockport. British Patent, 129,826, of 1918.

India-rubber is vulcanised in the cold by alternate treatment with sulphur dioxide and hydrogen sulphide, the two gases yielding sulphur within the substance of the rubber. A solution of hydrogen sulphide in benzene may be used instead of the gas after treatment with sulphur dioxide. The process may be used for the vulcanisation of rubber dissolved in a solvent such as benzene. Sulphur dioxide is passed into the solution, hydrogen sulphide is passed into a second solution, and the two solutions mixed; or one of the gases may be in solution in benzene.

Distilling Tobacco. H. Jephcott, London. British Patent, 129,491, of 1918.

Tobacco, tobacco stalks, and offal tobacco are distilled destructively in presence of an alkali such as lime, caustic soda, or potash, or the residual ash from the process, in a retort *a* provided with a mixing-device *c* and a coil *d* supplied with steam from a boiler *e* through a superheater *f*. The residual charred mass may be used as a fuel, and the ash used as a fertiliser or treated to extract potash. The vapours are

withdrawn by a pump *k*, which causes a reduced pressure in the retort, and are caused by valves *n* to pass through one or more absorbing-chambers *h* containing sulphuric, phosphoric, or other acid heated to the boiling-point by steam-jackets *i*, so as to remove only nicotine and ammonia. The remaining vapours are condensed in chambers *p*, and the condensate fractionated to separate acetone and methyl alcohol.

Monochloracetic Acid and Its Esters. L. J. Simon and G. Chavanne, Paris. British Patent, 129,301, of 1917.

Monochloracetic acid is prepared by direct hydration of trichlorethylene by means of hot sulphuric acid. The process may be carried out by dissolving trichlorethylene in highly concentrated sulphuric acid, adding water, and heating to 150-200° C., or by bringing vaporised trichlorethylene into intimate contact with sulphuric acid in suitable apparatus. The chloracetic acid may be separated by distillation, or by means of a current of hydrochloric acid gas or inert gas, or by diluting the solution and extracting with ether or other solvent. Esters of monochloracetic acid are obtained by adding an alcohol, e.g., ethyl alcohol—to the sulphuric acid solution and distilling.

Lead Chloride and Sulphate. F. E. Elmore, Boxmoor, Hertfordshire. British Patent, 129,773, of 1918.

In processes in which lead sulphate is extracted from ore products by brine or brine and sulphuric acid and subsequently separated from the solution, as in the process described in Specification 127,641, the accumulation of sodium sulphate in the brine is liable to interfere with the process. To regenerate the brine which has thus lost its efficiency, the solution is cooled to about 0° C., either before or after the separation of the lead salts. In the former case, lead salts and sodium sulphate separate out, and, after removal from the brine, which is then fit for use again, the mixture of salts is treated with hot, preferably boiling, water, whereby lead sul-

phate and brine are obtained; in the latter case, the sodium sulphate which separates is dissolved in hot water and used to treat the lead salts first separated, so as to obtain lead sulphate and brine as before, the treatment being preferably effected in a series of vessels on the counter-current principle. If silver is present, the lead salts may be boiled with water to extract lead chloride, the silver remaining with the residual lead sulphate, and the lead chloride is converted into sulphate by the sodium sulphate obtained as above described.

Picric Acid. J. N. Brooke, Lightcliffe, Halifax. British Patent, 129,375, of 1917.

Picric acid and other nitro compounds are continuously prepared in apparatus of the kind described in Specification 128,303, and the acid liquid issuing from the nitration vessels is passed through a cooler and filters, and then the filtrate is passed through one or more secondary nitration and concen-

tration units in which it is reheated to complete nitration and concentrate the liquor before final filtration. Using the apparatus shown, the acid liquid from the four primary nitration units 1 - 4 passes to a cooler 5 and thence to filters 6 - 9, in which the picric acid deposits; the filtrate then passes to secondary nitration and concentration units 10, 11 heated by steam coils, and is then filtered to separate more picric acid.

Chromium Sulphate. F. M. Mooney, Montreal, Canada. British Patent, 129,958, of 1919.

A chromate or bichromate is treated with an acid such as sulphuric acid to liberate chromic acid, and sodium thiosulphate is added to reduce the chromic acid. Heat is applied to expel the sulphur dioxide liberated, and the chromium oxide is filtered and washed and dissolved in sulphuric acid.

Furnaces. N. Testrup, and Techno-Chemical Laboratories. Clapham Park, London. British Patent, 129,771, of 1918.

In apparatus of the type described in Specification 115,087 for conducting continuous high-temperature reactions, the air or other gases for combustion are employed to cool the means for carrying the layer of material to be treated past the source of heat. As shown, material is fed from a hopper *d* to a plate *c'* and carried along by scrapers on an endless

chain. Air enters a trunk *c* below the plate *c'*, passes by passages *g*, *g*¹, *g*² of a regenerator, and meets either combustible gas or combustible material admixed with the layer at the left-hand end of the furnace. The fumes pass by passages *h*¹, *h*², *h*³ of the regenerator to a flue *h*⁴. Untreated material falls through a sieve *c*² and is returned to the hopper *d*.

Ammonium Sulphate. Oakbank Oil Company and J. Wishart, Glasgow. British Patent, 129,850, of 1918.

Neutral ammonium sulphate is obtained by introducing a measured quantity of ammonia liquor in the process of eliminating the mother-liquor from the sulphate by centrifugal or

equivalent apparatus. The ammonia liquor used is obtained direct from the crude ammonia still and contains ammonium carbonate.

Refractory Materials. H. M. Olson, Los Angeles; and H. W. Becker, Lompoc, California. British Patent, 129,505, of 1918.

A heat-insulating material which may be rendered abrasive by calcining consists of infusorial earth or non-crystalline silica in a finely divided state and a binder including aluminium sulphate or equivalent and an alkaline sulphate or a double sulphate of alumina or its equivalent and alkali. The composition may vary from 75 to 90 per cent. of infusorial earth and from 5 to 25 per cent. of binder. A preferable mixture consists of 88 per cent. of dry pulverised infusorial earth, 1 per cent sodium sulphate, 1 per cent. aluminium sulphate, and 10 per cent. lime. A suitable metallic sulphate equivalent may replace the aluminium sulphate, and other alkaline sulphate can be used instead of sodium sulphate; or a double sulphate of an alkali and alumina or equivalent may replace the two separate salts. The mixture is gauged or wet with water and moulded into bricks, etc. The mixture may be dried and calcined at from 800 to 2700° F., forming a hard crystalline substance having abrasive qualities.

Nitrates. H. E. F. Goold-Adams, Westminster; J. R. Partington, Lostock Gralam, Cheshire; and E. K. Rideal, Westminster. British Patent, 129,690, of 1917.

In the production of nitrates by absorption of nitrogen oxides (such as the products of the electric-arc oxidation of nitrogen or of the oxidation of ammonia) in solutions or suspensions of alkali, alkaline-earth, copper, zinc, or other compounds, a series of absorption towers or chambers is employed, the gas being passed through until the solution contains only nitrate, and the unabsorbed oxides being oxidised to nitrogen peroxide and led into the next absorption chamber. The apparatus may consist of a number of absorbers *a* in series, with oxidation chambers *c* inserted between consecutive

chambers having air inlets *d*; or each chamber may be large enough to provide oxidation space within itself, the chambers *c* being dispensed with. The gas is admitted at *g* and escapes at *i*, while the absorption liquid is admitted at *e* and passes from chamber to chamber by pipes *f*, escaping at the outlet *h*; or the gas and liquid may travel in the same direction. In a modification, Fig. 2, a number of absorption chambers *a* are arranged so that any chamber in which the liquor has become sufficiently nitrated can be cut out. The gas travels through the chambers in series and the absorption liquor is fed into, and discharged from, each chamber separately at *e* and *h* respectively. Intermediate oxidation chambers may be provided as shown in Fig. 1.

Hydrogen. E. K. Rideal, London, and H. S. Taylor, St. Helens. British Patent, 129,743, of 1918.

Hydrogen containing carbon monoxide as an impurity, for example hydrogen produced by liquefaction processes from water gas or by the steam iron process, is purified by submitting the gas successively to two processes by the first of which the greater part of the carbon monoxide is converted into carbon dioxide, while, by the second, the remainder of the carbon monoxide is removed by fractional combustion with air or oxygen. The impure hydrogen is mixed with steam and passed over a suitable catalyst, for example iron oxide admixed with one or more suitable promoters such as the oxides of chromium, cerium, or thorium, at a temperature of 400-500° C. The resulting mixture of gases is then cooled, mixed with a small quantity of air or oxygen, and passed over a second catalyst at a lower temperature. When using, as the second catalyst, iron oxide and a promoter of the kind mentioned

above, a temperature of 250-300° C. is employed; when using copper oxide, 120° C. is sufficient. The carbon dioxide is removed from the product by lime boxes or soda scrubbers, and oxygen, if present, is removed by passing the gases over a nickel catalyst at 200-300° C.

Denaturing Alcohol. A. F. Joseph, London. A communication from W. N. Rae and C. T. Symons, Colombo, Ceylon. British Patent, 129,904, of 1918.

A denaturant for alcohol consists of an essential oil or oils such as citronella with or without the addition of kerosene or paraffin oil, or mineral naphtha.

Purifying Hydrocarbons. G. F. Forwood and J. G. Taplay, London. British Patent, 129,349, of 1917.

Shale spirit, crude benzole, and other oils are treated for the removal of sulphur by washing with a solution of the sulphides of the alkalis or alkaline earths. The reagent may be prepared by saturating a strong solution of caustic potash with sulphuretted hydrogen and with flowers of sulphur in succession. The treatment may be effected by agitating the oil with the reagent for about six hours, or by heating them to about 40° C. The reagent is drawn off, and the oil is washed with water, then with dilute caustic soda solution, and finally with water.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Extracting Products from Shale. H. D. Ryan, York, Penn., U.S.A. British Patent, 129,992. Convention date, March 25, 1918.

In extracting bitumen, paraffin wax, and other constituents from shale, etc., the latter is digested with heavy oil at a temperature too low to effect destructive distillation, and the hot digest or solution is discharged into a bath of light oil in order to prevent the deposition of bitumen on cooling. The shale is fed by a screw conveyor 3 to a retort 2 containing a cylindrical screen 5 rotating in a bath of heavy oil 14 at a temperature of about 600°F; volatile constituents escape to a condensing coil 50 and refractory solid matter is discharged

from an outlet 11. The heavy oil digest flows through a pipe 16 into a conical tank 17 containing gasoline. Volatilised light oil escapes to a condenser 32 and is returned to the tank through a pipe 21, and the digest is carried by the upward current of light oil and delivered to tanks 36, 37, 38 containing heating coils 39 where light oil is again driven off to the condenser 32. Part of the digest is returned to the retort through a pipe 46 and the remainder is withdrawn through pipes 42 for further treatment. Clay, etc., is discharged from the tank 17 and conveyed through a heated chamber 25 for the recovery of light oil.

Separating Gaseous Mixtures by Liquefaction. E. Barbet and Fils and Cie., Paris. British Patent, 129,989. Convention date, July 17, 1918.

In the separation of air into its constituents by rectification of the liquid air, the rare gases, argon, helium, neon, krypton, and xenon are obtained in a pure state by a continuous rectification process. The proportions of the gases at various points in the primary and secondary rectifiers are maintained constant by the regulating devices described in

Specification 129,648. To diminish the nitrogen content of the crude argoniferous liquid, some twenty plates are arranged in the lower portion E of the primary rectifier A, Fig. 1, which is further cooled by the use of liquid air from the cooler U or of liquid nitrogen. The impure argoniferous liquid extracted at the point A² passes to a column 2-3, heated at the base by a nitrogen coil 13, which evaporates the oxygen collecting in the base; a portion of this oxygen passes through the pipe 11 to the gas-holder. The vapourised nitrogen from the coil 13 together with that from the coil of the air rectifier pass to the top of the latter. Rectification of the argoniferous mixture is effected by the plates 2, the vapours from the top of the rectifier passing to a condenser 4, the tubes of which are immersed in liquid nitrogen from

the top of the column A or elsewhere and thence to a separator 6, from which the gaseous portion passes back to the column A while the liquid passes back to the argon column through a pipe 8; pure argon is drawn off at the cock 10 and passes through a heat-exchanger, meter, and gas-holder. The reflux may be dispensed with when the argon is not required in a pure state, a smaller proportion being then liquefied in the condenser 4. In the neon and helium separator, Fig. 2, the impure nitrogen from the primary rectification process, containing neon, helium, and hydrogen, passes through a heat-exchanger A to a compressor B, water-cooler C, and back through the heat-exchanger A to a worm E immersed in pure liquid nitrogen in the base of a rectifier H; the vaporised nitrogen passes off to a gas-holder or to the top of the column. The impure nitrogen liquefied in the worm E is fed to the rectifier at the point F; pure nitrogen separates at the base, and a mixture of helium, neon, and hydrogen, free from nitrogen, issues at the top of the column through the pipe K and is compressed and cooled and passed to a coil G in the lower part of the rectifier, the pressure being sufficient to liquefy the whole of the neon and a portion of the hydrogen; the mixed liquid and gas are expanded in a separator P and the liquid passed to the top of the rectifier, pure neon being drawn off at the point Q; the gas passing off at the point p consisting of helium and hydrogen is passed through a heat-exchanger to a gas-holder, the hydrogen being destroyed by sparking with the oxygen or absorbed by wood charcoal. The mixture of oxygen with xenon and krypton coming from the primary rectifier may be freed of oxygen by sparking with hydrogen, but is preferably rectified directly in the apparatus shown in Fig. 3. The mixture is introduced in the liquid state at the point X where it is heated by the tubes Y having closed upper ends; the overflow of this liquid, almost free from oxygen, passes down the siphon tube 16 to the middle of the lower part of the column where it is rectified, pure xenon remaining at the base and being extracted at the point Xe. Krypton vapours contaminated with oxygen pass off through the pipe 17 from the top of the lower portion of the column and pure krypton is withdrawn a few plates lower at Cr¹. In the upper portion of the column, the oxygen is freed from krypton by condensation in the blind tubes Z which are cooled by liquid nitrogen, the condensate forming a reflux for the rectifying plates; pure oxygen drawn off at the point Oz may be passed to the gas-holder or to the base of the primary rectifying. The heating of the column is effected by a worm W through which dry air at about normal temperature is passed, the cooled air being used in the primary rectifier.

NEW COMPANIES.

Castelloid, Ltd.—Private company. Capital £5,000., £1. shares. Manufacturers of such articles as can conveniently be made in celluloid, casein or gelatine, etc. Registered office: 27, Britannia Street, Leicester.

The Bradford Concrete Block Company, Ltd.—Capital £2,000., £1. shares. Registered office: Empress Works, Legrams Lane, Bradford.

Insulators, Ltd.—Capital £75,000., £1. shares. Manufacturers of insulating and chemical materials and products, constructors of and dealers in plant, apparatus, and compounds used in the installation of cold storage premises, etc. Solicitor: R. S. Smallman, 8, Queen Street, E.C.

Kuala Hidong Rubber Estate, Ltd.—Capital £50,000., 2s. shares. Registered office: 107, Fenchurch Street, E.C.

Premier Briquette Company, Ltd.—Capital £125,000., in 120,000 preferred ordinary shares of £1. each and 100,000 ordinary shares of 1s. each. Manufacturers of and dealers in patent fuel, chemicals, fuel oil, etc. Registered office: 80, Coleman Street, E.C.

San Salvador Spanish Iron Ore Company (1919), Ltd.—Capital £126,000., £1. shares. Office: 80, Bishopsgate, E.C.2.

Alloy Castings, Ltd.—Private company. Capital £2,000., £1. shares. Founders, casters, merchants and brokers of, dealers in and agents for, silver, nickel-silver, brass, copper, gun-metal, bronze, aluminium, alloys, and all kinds of metals, etc. Registered office: Porter Works, Elin Street, Sheffield.

Anglo-Caribbean Petroleum Syndicate, Ltd.—Private company. Capital £25,000., £1. shares. Office: 13, Copthall Court, E.C.

Basic Fertilisers, Limited.—Private company. Capital £30,000., £1. shares. Manufacturers of and dealers in raw basic slag and all kinds of chemical fertilisers, etc. Registered office: 20, Copthall Avenue, E.C.

C. F. Gerhardt, Ltd.—Private company. Capital £30,000., in 12,000 7 per cent. cumulative preference and 18,000 ordinary shares of £1. each. Importers and exporters of and dealers in drugs, chemicals, drysalteries, minerals, and produce, etc. Registered office: 5, Fenchurch Street, E.C.

Chemical Engineering Company (Manchester), Ltd.—Private company. Capital £15,000., £1. shares. Qualification 1 ordinary share. Registered office: 49, Deansgate, Manchester.

Ebo Rubber, Ltd.—Private company. Capital £3,000., £1. shares. Registered office: "A" Warehouse, 3rd Section Seal Wharf, Stratford, E.

Hays Marine Waterproof Glue Company, Ltd.—Private company. Capital £6,000., £10. shares. Objects: To take over the business carried on by the Hays Waterproof Glue and New Patent Enamel, Composition, and Varnish Company, Ltd. Solicitor: F. O. Goodman, 24a, Commercial Road, Portsmouth.

H. M. Leask and Co., Ltd.—Private company. Capital £50,000., £1. shares. Object: To acquire the business of H. M. Leask, seed crushers, cake and oil manufacturers, oil refiners, soap boilers, etc. Registered office: 14-15, Sir John Rogerson's Quay, Dublin.

Irish Color Manufacturing Company, Ltd.—Private company. Capital £1,000., £1. shares. Object: To carry on business as manufacturers' dealers in oils and varnishes, etc. Solicitors: Pedan and Reid, 64, Donegal Street, Belfast.

Victor Chemical Company, Ltd.—Private company. Capital £1,000., £1. shares. Registered office: 81, Duncan Gardens, Belfast.

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Aladdin Cobalt, Ltd.—Meeting of creditors at 638, Salisbury House, E.S., September 24.

Copal Varnish Company, Ltd.—Meeting of creditors at Sherwood House, Piccadilly Circus, W., September 18.

Lynn Chemical Engineering Company, Ltd.—London, S.W. Resolved August 20, confirmed September 9: That the company be wound up. F. W. Stephens, 26-30, Salisbury House, London Wall, E.C., I.A., liquidator.

Southern Californian Oil Syndicate, Ltd.—London, E.C. Resolved August 27, confirmed September 12: That the company be wound up. M. H. Adams, 3, Gerrard Street, W., liquidator. Meeting of creditors at liquidator's, September 29, at 3 p.m.

DISSOLUTIONS OF PARTNERSHIP.

(Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.)

Crooke R., Junior, and Co.—(Reginald Crooke, deceased, and Norman Crooke), 11, Dale Street, Liverpool, oil and produce brokers. June 30. The business will in future be carried on under the same style by Frederick Graham, by whom the liabilities of the late partnership will be discharged. (September 12.)

ACETIC ACID IN CHESTNUT EXTRACT.—Writing on "The Leather Industry during the War," U. J. Thauau, in *Le Cuir*, mentions the recovery of acetic acid in the manufacture of chestnut extract. During concentration of the liquors in the triple-effect evaporation the acid is found in the water of condensation from the second and third cylinders, and in the method used by the Comptoir des Extraits, condensation waters are used over again for the extraction of the wood. The presence of acetic acid favours an easy extraction, and works trials have proved that extracts so prepared are of better quality and contain less non-tans than those prepared with ordinary water. Such facts would appear to indicate that acetic acid acts as a stabiliser towards the pyrogallol tannin. It is concluded, therefore, that it is not a good practice to recover for other purposes the acetic acid (i.e., for the manufacture of pure acetic acid), as it is equally bad both for the extract maker and tanner, the latter knowing quite well the swelling properties of acid in their liquors.—*Leather World*.

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London 90%, 2s.; North, 1s. 9d. to 1s. 10d.; 50%, 1s. 10d. to 1s. 11d.; North, 1s. 9d. to 1s. 10d. naked. **Carbolic acid,** crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 9d. to 9½d., f.o.b. **Crude tar,** London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. **Pitch,** 77s. 6d. to 80s.; East Coast, 67s. 6d. to 75s., f.o.b.; West Coast, 62s. 6d. to 65s., f.a.s. **Solvent naphtha,** naked, London, 90-190%, 2s. 5d.; North,

2s. 3d. to 2s. 4d.; 90-160%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. **Crude naphtha** naked, 30%, 9d.; North, 8d. to 8½d. **Refined naphthaline,** £16. to £18.; salts, £6. to £7. **Toluol,** naked, London, 2s. 6d.; North, 2s. 5d. **Creosote,** naked, London, 6½d.; North, 5½d. to 5¾d.; heavy oil, 6½d. **Anthracene,** 40-45%, 7d. per unit. **Cresylic acid,** 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b., other ports. **Sulphate of ammonia;** home trade, September, £19. 10s. per ton.; October, £20. 10s., basis 24½%. **Nitrate of soda,** £22. to £22. 10s.

FERTILISER MATERIALS.**LIVERPOOL, THURSDAY.**

Nitrate of soda is quiet on spot, and today's quotation for 95-96% quality is £20. 2s. 6d. per ton, net cash, f.o.r. Liverpool, prompt delivery. East Indian bone meal for shipment is without alteration, the quotation for October-December shipment being £17. 10s. per ton, net cash, ex ship Liverpool, for 1½% ammonia, and 52% phosphates. On spot Liverpool holders ask £16. per ton, net cash, for 1½% and 45% quality. Mineral phosphates: There is no change to report in this material, and values at present are only nominal. Dried blood is rather irregular, the nearest value being about 30s. per unit of ammonia per ton, net cash.

LONDON METAL MARKET.**THURSDAY.**

Copper: Standard brands, £99. 15s. to £100. cash; £100. 5s. to £100. 10s. three months; electrolytic, £110. to £121. Tin: Standard, £277. to £277. 10s. cash; £274. 15s. to £275. three months; Straits, £277.; English, £274. to £275. Lead: Soft foreign, £25. 12s. 6d.; English, £26. 15s. Spelter, £41. 10s.; hard, £28. to £30. Antimony, English regulus, 90%, £45. Aluminium £150. Nickel £205. delivered, packages extra. Quicksilver £23. 10s. to £24. Bismuth 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

TURPENTINE MARKET REPORT.

Messrs. James Watt and Son, Ltd., 101, Leadenhall Street, London, E.C. 3, report that the stocks of turpentine on September 27 were: American, 30,505 barrels, compared with 5,689 barrels at the corresponding date of 1918; French, 487 barrels (453 barrels); and Spanish, 524 barrels (455 barrels). Deliveries during the week ended September 20 were 1,944 barrels against 440 barrels last year, and since January 1 52,790 barrels, compared with 17,951 barrels in 1918. The price on Saturday last was 128s. 6d., compared with 105s. at the corresponding date of last year. October-December delivery was quoted at 130s., and January-April (1920), 131s. 9d.

MANCHESTER CHEMICAL MARKET.**THURSDAY.**

Business generally continues satisfactory, with a steady volume of trade both for home and export. Quotations all round are firm. Caustic soda is dearer, and £22. now asked for resale lots of 76/77% 58% alkali, £7. net per ton ex store. Refined bicarbonate of soda, bags, £7. 10s. per ton. There is not much inquiry for bleaching powder, and price is easy at £15., softwoods, on rails; soda crystals and saltcake unchanged at recent rates. Chlorate of soda lower at 6d. per lb. Potash dull at 1s. per lb. Bichromates unaltered. Recovered rock sulphur £17. rails makers' works. Demand for copper sulphate continues flat, and price nominal at £41. per ton, f.o.b. Phosphate of soda firmer at £26. per ton. Comm'l. hypophosphate of soda steady at £16. 10s. per ton. Concentrated sodium sulphide higher, at £23. casks on rails. Nitrate of soda, £21. per ton. White powdered arsenic still scarce, and £60. quoted for small parcels. Yellow prussiate of soda is higher on the week at 10d. per lb., and supplies short. Prussiate of potash steady at 1s. 9d. per lb. For lead salts there is fair inquiry, and prices are well maintained. White acetate, £83.; brown, £69.; and nitrate, £56. per ton. Acetate of soda and acetic acid are unaltered at recent rates. English brown acetate of lime, £11. per ton., grey, £17. per ton. Miscible wood naphtha dearer, at 10s. 6d. per gall. Nitrite of soda scarce on the spot at £60., basis 100%. Green copperas still moves slowly, and price easy. Oxalic acid steady at 1s. 2½d. per lb. delivered.

LIVERPOOL CHEMICAL MARKET.**THURSDAY.**

Inquiries for chemicals have come to hand more freely, the demand on export account having further increased. More interest generally has been shown, in covering for forward dates, in view of the continued shortage of supplies of some of the heavier goods for immediate or early deliveries. Bleaching powder has been more in request for U.K. use and for export. The price may be given as £17. per ton free on rail or conveyance, in buyers' packages. Chloride of calcium has been in very fair demand, and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has again been well inquired for, and, with a moderate supply, is less readily obtainable. Prices are: £24. per ton for 76%; £22. per ton for 70 to 72%; and £19. per ton for 60 to 62%. Nitrate of soda has been more in request, and is £21. to £22. per ton. Saltcake has met with

a rather active inquiry, and is £6. 10s. per ton, in casks, f.o.b. Soda crystals have sold with some freedom, and are £5. 10s. per ton, in 2cwt. bags, f.o.r. at works. Bicarbonate of soda has been in active demand, and is £7. 5s. to £10. per ton, according to terms of delivery. Borax has been in good request, and English continues in small supply. Quotations for it are £42. per ton for ordinary, and £44. per ton for powdered, in bags. Ammonia alkali has been in brisk demand, and is £6. 15s. per ton, f.o.r. at works. Hyposulphite has been in fair request, and is £16. per ton for ordinary, and £21. per ton for pea crystals, in 1cwt. kegs. Sulphite of sodium has been quiet, and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals in 1cwt. kegs. Bichromate of soda has been more inquired for, and is 9d. per lb. Phosphate of soda has been in moderate request, and is £25. per ton. Sulphide of sodium has been but little called for, and is £20. per ton in casks, and £22. per ton in drums. Chlorate of potash has been in fair demand, and is 1s. to 1s. 2d. per lb. Permanganate of potash has been rather more in request, and is 3s. 3d. to 3s. 6d. per lb. Sulphate of potash has moved but slowly, and is £30. per ton. Carbonate of potash has been in quietly steady demand, and is £90. to £95. per ton for 80 to 85%. Caustic potash has been well inquired for, and is £110. to £120. per ton. Nitrate of potash has sold with some freedom, and is £55. to £60. per ton for refined, and £40. per ton for ordinary. Canadian potashes have been neglected. Montreal first quality are £200. to £220. per ton, and second quality, £190. to £210. Bichromate of potash has sold more readily, and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been in very fair demand, and is 1s. 9d. to 1s. 10d. per lb. Sal ammoniac has been steadily called for, and is £80. per ton for lump, £75. per ton for seconds, and £5. per ton extra for ground. Sulphate of ammonia has sold a little more freely, and is £19. 10s. per ton for September; £20. 10s. for October; £20. 15s. for November; £21. for December; £21. 7s. 6d. for January, 1920; £21. 15s. for February, and £22. per ton for March to May, 1920. Carbonate of ammonia has been in moderate inquiry, and is 6½d. per lb. Muriate has had a very limited sale, and is £45. to £50. per ton, according to quality. Magnesia has again met with a fair inquiry. Carbonate is £2. 5s. per cwt., and sulphate, £10. to £16. per ton, according to grade. Alum continues to be well inquired for, and little of it has been available for early deliveries. Prices are: £18. 10s. per ton for the home trade, and £18. 10s. to £19. 10s. per ton for export. Aluminoferric has been in slightly better request, and is £8. 10s. to £12. per ton, according to quality. Sulphate of alumina has been more inquired for, and is £12. to £17. per ton according to grade. Sulphur has been in good request, and English flowers are still in small supply. They are £32. per ton. Roll is £23. per ton, and rock £22. per ton, in bags, f.o.r. Sicilian grades are: Flowers, £28. per ton; roll, £22. 10s. per ton; and rock, £17. 15s. per ton. Cream of tartar has been quieter, and is £11. 10s. to £11. 15s. per cwt. Tartaric acid has been in quietly steady demand, and is 3s. 2d. to 3s. 3d. per lb. Boracic acid has been in very fair request, and is £72. per ton for crystals, and £74. per ton for powdered. Oxalic acid has been in somewhat freer inquiry, and is 1s. 2d. to 1s. 3d. per lb., according to requirements for delivery. Citric acid has been in fair request, and is 4s. 4d. per lb. White acetate of lead has been quiet, and is £83. to £85. per ton. Arsenic has been more inquired for, and high prices continue to be quoted for white powdered. From £58. to £60. may be given as present prices of this grade. Sulphate of copper has been neglected, and is £40. to £41. per ton for use in the United Kingdom.

TYNE CHEMICAL REPORT.**TUESDAY.**

The demand for heavy chemicals continues good, and there is more inquiry for export. Bleaching powder and caustic soda are in good request. Sulphur is scarce and firm at £22. 10s. to £23. per ton. Soda crystals locally in strong request at £5. 10s. per ton, 2cwt. bags. The following prices are per ton net: Bleaching powder, softs, £17.; caustic soda 74 to 77%, £23. 5s.; do., 70%, £22.; do., 60%, £20.; recovered sulphur, 2cwt. bags, £23.; hyposulphite of soda, 5/7cwt. casks, £19.; 1cwt. kegs, £25.; sulphite of soda, 5/7cwt. casks, £12.; do., 1cwt. kegs, £20.; silicate of soda, 75° Tw., £9. 12s. 6d.; do., 100° Tw., £10.; do., 140° Tw., £10. 10s.; soda crystals, 2cwt. bags, £5. 10s.; sulphate of soda (salt cake) in bulk, £4.; pure white sulphate of alumina, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18. per ton net.; do., refined concentrated solid, 60/62%, £25. per ton net.; hydrate of barium crystals, £56. per ton net.

COALS.—Market remains steady, and recent prices are well maintained. There is a strong demand for export, and any surplus is quickly taken up. Prices nominally: Best Northumbrian steam coals, 95s. to 100s. per ton; second qualities, 90s. to 95s.; Northumberland small coals, 75s. to 80s.; seconds, 70s. to 75s.; best Durham gas coals, 80s. to 85s.; seconds, 65s. to 75s.; Durham bunker, 70s. to 80s.; seconds, 65s. to 67s. 6d.; foundry coke, 100s.; gas coke, 95s. to 100s.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Wednesday.

During the past week there has been a fair volume of business transacted in the local chemical market, and quotations continue on a steady level. There has been an increase in the bigger class of deal—so it is currently reported, at any rate,—but in many cases the small bulk order still holds sway. The latest range of prices shows few changes, but if anything tartaric acid has been inclined to harden. Prices current are: Arsenic, £60. per ton, net, Glasgow; bicarbonate of soda, £8. 15s. and £10. per ton, for 6-8 casks and 1cwt. kegs, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags, and borax crystals, £39. for 2cwt.

bags, carriage paid; caustic soda, white, 70-72%, £24. per ton, net, Glasgow; chlorate of potash, 1s. 1d. per lb., net, Glasgow; chlorate of soda, 8d. per lb., net, Glasgow; citric acid, 4s. 4d. per lb. 5% Glasgow; cream of tartar 98% £11. 5s. per cwt., net, Glasgow; paraffin wax U.K. deliveries 125°, 6½d. to 6¼d.; 121-3°, 5¼d. to 5¼d.; 118-20°, 5d.; 110-12°, 4d. to 4¼d.; and 98-102°, 4d. to 4¼d.; salammoniac, £80. and £75. per ton, net, any port, for first and second lump respectively; salammoniac crystals, £85. per ton, net, Glasgow; saltpetre, £3. 4s. net, Glasgow; tartaric acid, 3s. 2d. per lb., 5% Glasgow.

Among the sea oils the only change as far as values are concerned is with regard to Newfoundland cod, and this is now quoted at 80s. as against 79s. previously. All available quantities continue to go into quick consumption, and the same comment is also applicable to pale seal at its unchanged quotation of 96s., and Menhaden at its old figure of 86s. Whale oils also keep at the old levels of 97s. for pale, 76s. for brown, and 74s. for black, with no yellow still available.

In the Glasgow and West of Scotland coal trade conditions remain the same—with most of the output continuing to be absorbed for home purposes. On the export side there continues to be little or nothing doing.

IMPORTS OF CHEMICAL PRODUCTS

AT THE PRINCIPAL PORTS OF THE UNITED KINGDOM.

BRISTOL.

Publication of Official Returns
Suspended.

GLASGOW.

Week ending September 20.

ACETONE—
Baltimore, 250 drms.

Antwerp, 3 drms., £88.; Rotterdam, 10 drms., £349.; Singapore, 2 pkgs. (pt.), £14.

AMMONIA—

Antwerp, 2 drms., £10.; Buenos Ayres, 10 pkgs., £26.; Cape Town, 12 cs., £23.; Colombo, 4 cs., £8.; Constantinople, 4 cs., £8.; Durban, 44 cs., £65.; Hong Kong, 9 cs., £18.; Lisbon, 54 crbys., £84.; Pt. Elizabeth, 4 cs., £8.; Shanghai, 15 cs., £29.; Soerabaya, 5 cs., £7.

AMMONIA (ANHYDROUS)—

Alexandria, 3 cylds., £30.

AMMONIUM BENZOATE—

Sao Paulo, 2 pkgs. (pt.), £16.

AMMONIUM CARBONATE—

Antwerp, 1 t. 15 c., £106.; Buenos Ayres, 10 c., £37.; Calcutta, 2 t., £145.; Cologne, 10 t., £601.; Coquimbo, 1 t. 2 c., £108.; Genoa, 24 t. 12 c., £1,327.; Monte Video, 1 t. 15 c., £175.; Padang, 10 c., £38.; Penang, 6 c., £23.; Perth, 5 c., £23.; Pt. Elizabeth, 2 c., £9.; Rio de Janeiro, 5 t. 1 c., £586.; Santiago, Chile, 1 t. 12 c., £134.; Sao Paulo, 5 c., £24.; Talcahuano, 20 c., £84.

AMMONIUM CHLORIDE—

Bangkok, 2 pkgs., £14.; Calcutta, 2 cs., £15.; Geelong, 3 kgs., £10.

AMMONIUM FLUORIDE—

Mauritius, 2 cs., £30.

AMMONIUM MURIATE—

Auckland, 2 c., £9.; Adelaide, 3 c., £11.; Constantinople, 2 c., £7.; Galatz, 1 t., £55.; Madras, 4 c., £17.; Santiago, Chile, 1 t. 6 c., £156.; Valparaiso, 11 c., £60.

AMMONIUM PHOSPHATE—

Copenhagen, 10 c., £60.; Piraeus, 1 t., £112.

AMMONIUM SULPHATE—

Dunkirk, 193 t. 14 c., £4,840.; Kobe, 200 t., £4,600.

AMYL ACETATE—

Paris, 13 drms., £161.

ANTIMONY (CRUDE)—

Rio de Janeiro, 15 c.

ANTIMONY OXIDE—

Genoa, 40 cks., £160.

ANTIMONY REGULUS—

Antwerp, 1 t.

ANTIMONY SULPHIDE—

Bahia, 10 cks., £22.; Boston, 15 cks., £347.; Dunkirk, 1 ck., £32.; Demerara, 3 bgs., £6.; Lisbon, 20 kgs., £55.; Paris, 21 cks., £392.

ARSENIC

Beyrou (F.), 10 c., £32.; Genoa, 1 t. 3 c., £39.; Rio de Janeiro, 1 t. 3 c., £92.; Santos, 1 t., £53.; Sao Paulo, 3 t., £156.

BARIUM SULPHIDE

Christchurch, 2 cks., £6.

BASIC SLAG

Belewan, 400 t., £1,600.; New Plymouth, 200 t., £750.

BEES WAX

Amsterdam, 4 c.

BENZOIC ACID

Genoa, 1 cs., £55.; New York, 2 cs., £75.

BISMUTH CARBONATE

Auckland, 1 cs. (pt.), £8.; Buenos Ayres, 1 cs. (pt.), 12 cs., £719.; Cape Town, 1 cs. (pt.), £40.; Wellington, 1 cs. (pt.), £14.

BISMUTH GALLATE

Buenos Ayres, 1 cs. (pt.), £17.

BISMUTH SALICYLATE

Buenos Ayres, 2 cs., £72.; Singapore, 1 cs. (pt.), £13.

BISMUTH SUBNITRATE

Buenos Ayres, 1 cs., £76.; Cape Town, 1 cs. (pt.), £18.; Calcutta, 2 cs., £160.

BITROPHOSPHATE

East London, 1 cs. (pt.), £13.

BITUMINOUS SOLUTION

Punta Arenas, 30 drms., £91.

BLEACHING POWDER

Bangkok, 2 c., £6.

BORIC ACID

Calcutta, 1 t. 11 c. (F.), £120.; Haifa, 1 c., £5.; Madras, 7 c., £35.; Rosario, 4 c., £15.

BORAX

Antwerp, 19 t. 18 c., £1,000.; Switzerland (via Antwerp), 9 t. 17 c., £394.; Auckland, 2 c., £5.; Cologne, 20 t., £772.; Delagoa Bay, 2 c., £9.; Durban, 6 c., £26.; Jamaica, 15 c., £30.; Malta, 10 c., £20.; Paris, 20 t., £780.; Punta Arenas, 2 c., £6.

CALCIUM CARBIDE

Amsterdam, 25 t., £606.

CALCIUM CARBONATE

Antwerp, 2 cks., £5.; Buenos Ayres, 2 cks., £6.

CALCIUM CHLORIDE

Sydney, 1 t. 3 c., £45.

CALCIUM GLYCEROPHOSPHATE

Antwerp, 1 cs. (pt.), £6.

CALCIUM HYPOPHOSPHATE

Genoa, 2 cs., £45.

CARBON BISULPHATE

Novorossisk, 5 t., £540.

CAUSTIC POTASH

Cape Town, 1 cs. (pt.), £13.

CAUSTIC SODA

Cape Town, 5 c., £6.; Malmo, 10 t. 3 c., £220.; Rotterdam, 31 t. 14 c., £635.; Shanghai, 4 c., £13.

CERESINE WAX

Amsterdam, 1 t.; Genoa, £370.; Helsingfors, £63.; Malmo, 14 c.; Wellington, 2 t.

CHEMICALS (otherwise undescribed)

Alexandria, 1 cs., £29.; Athens, 1 cs. (pt.), £7.; Bangkok, 1 cs. (pt.), £7.; Beyrou, 1 cs., £8.; Calcutta, 2 cs., £16.; Cape Town, 1 cs., £8.; Durban, 1 cs., £7.; Foochow, 2 cs., £9.; Hong Kong, 2 cs., £14.; Iddo, 3 cs., £66.; Mombasa, 1 cs., £9.; Singapore, 2 cs., £42.; Socrabaya, 3 cs., £159.; Sydney, 8 cs., £250.; Wellington, 1 cs., £10.; Zanzibar, 2 cs., £21.

CITRIC ACID

Aden, 4 c., £102.; Calcutta, 1 c. (F.), £27.; Calcutta, 5 c., £115.; Dantzig, 10 c. (F.), £230.; Durban, 3 c., £72.; East London, 2 c. (F.), £29.; Fremantle, 1 c., £26.; Hastings, N.Z., 1 c. (F.), £15.; Limon, 1 c., £25.; Montreal, 1 t. 5 c., £565.; Penang, 1 c., £26.; St. Helena, 1 cs. (pt.), (F.), £6.; Shanghai, 3 c., £60.

CITRIC ACID

Thursday Island, 2 c., £50.

COAL PRODUCTS

Aniline Dye
Adelaide, 1 pkg., £35.; Auckland 7 pkgs., £199.; Brussels, 6 pkgs., £131.; Gothenburg, 1 kg., £66.; Lyttleton, 6 pkgs. (pt.), £201.; Malmo, 1 cs., £39.; Melbourne, 17 pkgs., £799.; Oaman, 1 ck., £56.; Perth, 2p kgs., £41.; Sydney, 1 cs., £30.; Wellington, 1 cs., £40.

Aniline Oil

Brussels, 1 cs., £9.

Bitumen

Calcutta, 6 cks., £34.

Carbolic Acid

Calcutta, 5 drms., £7.; Kobe, 79 cks., £472.; Pt. Elizabeth, 2 cs., £5.; Santos, 2 cs., £9.; Singapore, 1 cs., £8.

Cresote

Antofagasta, 13 drms., £8.; Hong Kong, 10 cks., £60.; Rio de Janeiro, 1 cs. (pt.), £5.

Cresote Salts

Constantinople, 40 brls., £65.; Smyrna, 40 brls., £66.

Naphthalene

Adelaide, 25 cs., £125.; Alexandria, 20 cks., £49.; Beira, 1 cs., £5.; Brussels, 2 kgs., £7.; Calcutta, 50 cs., £110.; Paris, 19 cks., £1,914.

Pitch

Antwerp, 538 t., 60 brls., £2,247.

Tar

Beira, 165 drms., £19.; Suez, 2 drms., £9.

Tar Oil

Monte Video, 50 cks., £133.

Terebine

Durban, 3 cs., £10.; Perth, 2 cs., £11.

COPPER SULPHATE

Bissao, 2 c., £6.; Calcutta, 4 c., £6.; Paramaribo, 1 t. 10 c., £59.; Rangoon, 5 c., £13.

CREAM OF TARTAR

Bombay, 1 c. (F.), £13.; Copenhagen, 10 c., £125.; Callao, 2 c., £34.; Cape Town, 2 c. (F.), £34.; Calcutta, 7 c. (F.), £136.; Calcutta, 1 pkgs., £7.; Delagoa Bay, 2 c. (F.), £32.; Durban, 1 c. (F.), £16.; East London, 2 c. (F.), £30.; Hong Kong, 2 c. (F.), £30.; Karachi, 1 cs. (F.), £5.; Pt. Elizabeth, 4 c. (F.) (F.), £65.; Pt. Elizabeth, 5 c., £29.; Rio de Janeiro, 4 c., £50.; Santos, 1 c., £13.; Santiago, Chile, 10 c., £168.; Wellington, 4 t. (F.), £830.

DISINFECTANTS (otherwise undes.)

Antwerp (F.), 5 t., £630.; Athens, 2 t. 13 c., £410.; Auckland, 7 c., £106.; Belawan, 5 c., £12.; Benguela, 8 c., £31.; Beira, 2 c., £25.; Brisbane, 5 c., £8.; Buenos Ayres, 32 t. 16 c., £1,490.; Cairns, 5 c., £14.; Calcutta, 4 t. 8 c., £159.; Christchurch, 2 c., £20.; Delagoa Bay, 15 c., £43.; Dunedin, 1 t. 2 c., £123.; Durban, 8 t. 16 c., £596.; Invercargill, 13 c., £39.; Karachi, 13 c., £25.; Lisbon (F.), 6 c., £33.; Lisbon, 8 c., £65.; Lyttleton, 17 c., £108.; Mauritius, 5 c., £8.; Penang, 18 c., £29.; Pernambuco, 5 c., £13.; Perth, 8 c., £20.; Pt. Swettenham, 5 t. 11 c., £250.; Sandakan, 9 c., £16.; Suez, 5 c., £12.; Wellington, 1 t. 2 c., £177.

DYESTUFFS

Tanning Crystals

Calcutta, 5 cks., £73.

ETHER

Buenos Ayres, 1 cs., £10.

ETHER (ACETIC)

Lisbon, 1 cs., £6.

FULLER'S EARTH

Bombay, 5 t.

GLUE

Antwerp, 16 t. 17 c.; Malmo, 4 c.; Novorossisk, 5 c.

GLUE, SIZE, AND GELATINE

Adelaide, 1 t. 10 c.; Antwerp, 7 c.; Bilbao, 10 c.; Bombay, 2 t. 5 c.; Boulogne, 1 c.; Cape Town, 1 t. 5 c.; Calcutta, 3 c.; Christchurch, 1 c.; Cyprus, 11 c.; Dunedin, 3 c.; Dieppe, 3 t. 4 c.; Durban, 3 c.; East London, 1 c.; Karachi, 1 c.; Kobe, 2 t.; Madras, 5 c.; Melbourne, 10 c.; New York, 1 c.; Perth, 5 c.; Pt. Elizabeth, 2 c.; Rotterdam, 3 c.; Singapore, 1 c.; Wellington, 1 t.; Yokohama, 4 t.

GLYCERINE

Bangkok, 1 c., £10.; Bombay, 2 c., £13.; Calcutta, 3 c., £34.; Galatz, 1 c., £8.; Hong Kong, 4 c., £28.; Karachi, 1 c., £15.; Paris, 3 t. 2 c., £390.; Rosario, 4 c., £30.; Salonic, 1 c., £6.; Samarang, 1 c., £5.; Talcahuano, 1 t., £150.; Yokohama, 9 c., £154.

HEXAMETHYLENETETRAMINE

Constantinople (F.), 2 cs., £34.

HYDROBROMIC ACID

Calcutta, 1 cs., £13.

HYDROCHLORIC ACID

Belawan, 1 c., £6.; Calcutta, 3 c., £12.; East London, 12 c., £35.

HYDROGEN PEROXIDE

Alexandria, 1 cs., £9.; Durban, 1 cs., £6.; Pt. Elizabeth, 2 cs., £8.

HYPOPHOSPHITES

Christchurch, 1 cs., £18.; Genoa, 2 cs., £88.

HYPOPHOSPHITE SALTS

Paris, 5 cs., £114.

INFUSORIAL EARTH

Paranagua, 16 c., £21.; Rio de Janeiro, 1 t. 2 c., £27.; Santos, 12 c., £16.

IODINE

Perth, 3 cs. (pt.), £23.

IODINE (RESUBLIMED)

Antwerp, 1 cs. (pt.), £48.; Buenos Ayres, 1 cs., £45.; Genoa, 2 cs. (pt.), £91.; Lisbon, 1 cs. (pt.), £9.

IRON AND AMMONIUM CITRATE

Antwerp, 1 cs. (pt.), £17.; Buenos Ayres, 1 cs. (pt.), 2 cs., £59.; Shanghai, 1 cs., £42.

IRON & POTASSIUM CYANIDE

Antwerp, 1 cs. (pt.), £13.

IRON PERCHLORIDE

Batavia, 1 cs., £5.; Buenos Ayres, 21 pkgs., £20.; Santos, 2 cs., £5.

IRON PYROPHOSPHATE

Montreal, 1 cs., £13.

KEISELGHUR

Calcutta, 10 c., £8.

LACTIC ACID

Havre (F.), 1 ck., £15.

LEAD ACETATE

Antwerp, 1 kg., £11.; Bombay, 20 cks., £70.; Calcutta, 1 cs. (pt.), £9.; Cape Town, 2 kgs., £13.; East London, 3 kgs., £18.

LEAD CARBONATE

Sao Paulo, 2 cs., £19.

LEAD LINOLEATE

Brussels, 3 brls., £78.

LEAD RESINATE

Messina, 1 ck., £6.

LITHIUM BENZOATE

Constantinople, 1 cs. (pt.), £17.; Rio de Janeiro, 1 cs. (pt.), £8.

LITHIUM CARBONATE

Genoa, 2 cs., £95.

MAGNESIA (CALCINED)

Antwerp, 1 cs., £8.; Bordeaux, 4 cs., £84.; Sao Paulo, 5 pkgs. (pt.), £72.

MAGNESIUM CARBONATE

Auckland, 1 cs., £6.; Adelaide, 6 cs., £16.; Genoa, 50 cs., £119.; Lisbon, 10 cs., £37.; Punta Arenas, 1 cs., £9.; Rio de Janeiro, 9 cs., £79.; Rosario, 7 cs., £28.

MAGNESIUM CARBONATE

Sao Paulo, 5 cs., £44.

MAGNESIUM CITRATE

Auckland, 2 cs., £28.; Calcutta, 1 cs. (pt.), £6.; Christchurch, 2 cs., £16.

MAGNESIUM HYDRATE

Switzerland, 8 pkgs., £28.

MAGNESIUM OXIDE

Leghorn, 6 cks., £36.

MAGNESIUM SULPHATE

Auckland, 2 t., £78.; Beira, 4 c., £9.; Bermuda, 11 c., £23.; Bombay, 17 c., £57.; Colon, 3 c., £7.; Galatz, 1 t., £38.; Hastings, 10 c., £19.; Karachi, 5 c., £13.; Limon, 10 c., £24.; Melbourne, 2 t. 6 c., £98.; Napier, 10 c., £19.; Panama, 11 c., £26.; Porto Alegre, 27 c., £68.; Sydney, 12 c., £22.

MANGANESE BINOXIDE

Antwerp, 5 cks., £42.

MANGANESE HYPOPHOSPHITE

Montreal, 4 cs., £123.

MANGANESE LINOLEATE

Brussels, 1 brl., £18.

MERCURIALS

Lisbon, 1 cs. (pt.), £7.

MERCURY AMMONIATE

Calcutta, 3 cs., £145.

MERCURY BICHLORIDE

Lisbon, 1 cs., £47.

MERCURY CHLORIDE

Buenos Ayres, 2 cs., £101.

MERCURY IODIDE

Constantinople, 2 cs. (pt.), £25.; Swatow, 1 cs. (pt.), £6.

MERCURY OXIDE

East London, 1 cs. (pt.), £6.

MERCURY PERCHLORIDE

Calcutta, 1 cs., £6.; Santos, 4 cs., £148.

MERCURY PRECIPITATE

Helsingfors, 1 cs. (pt.), £23.

MERCURY SALICYLATE

Constantinople, 1 cs. (pt.), £6.

METHYL ALCOHOL

Amsterdam, £350.

METHYL SALICYLATE

Antwerp (F.), 1 cs. (pt.), £13.; Buenos Ayres (F.), 1 cs. (pt.), £10.; Constantinople (F.), 1 cs., £22.; Sao Paulo, 1 cs., £6.

NICKEL SALTS

Malmo, 3 cks., £25.

NITRIC ACID

Bangkok, 1 c., £6.; Belewan, 1 c., £5.

OXALIC ACID

Melbourne, 4 cks., £135.

PARAFFIN WAX

Antwerp, 1 t. 9 c.; Paris, 20 t. 10 c.

PARALDEHYDE

Perth (F.), 1 cs., £22.

PHENIC ACID

Antwerp (F.), 1 cs., £9.; Rosario, 2 cs., £5.

PHOSPHO CITRIC ACID

Cape Town, 5 c., £39.

PHOSPHORIC ACID

Adelaide, 3 cs. (pt.), £7.; Calcutta, 1 cs., £9.; Antwerp, 1 cs., £9.; Montreal, 22 pkgs., £198.; Pernambuco, 3 cs., £30.; Paris, 30 crbys., £334.

PHOSPHORUS

Antwerp, 1 cs., £6.

PHOSPHORUS AMORPHOUS

Durban, 20 cs., £242.

PLUMBAGO

Launceston, 1 t.; Pt. Elizabeth, 1 t.; Rio de Janeiro, 19 c.

POTASSIUM & TARTARIC ACID

Singapore, 1 cs. (pt.), £8.

POTASSIUM BICARBONATE

Christchurch, 1 kg., £7.; Melbourne, 1 bkg., £7.; Singapore, 1 kg. (pt.), £5.

POTASSIUM BICROMATE

Demerara, 1 rl., £17.; Lyttleton 1 kg., £9.

POTASSIUM BROMIDE—

Buenos Ayres (F.), 1 cs. (pt.), £9.; Cape Town (F.), 1 cs. (pt.), £10.; Rosario, 2 cs., £17.; Santos, 1 cs. (pt.), £12.

POTASSIUM CARBONATE—

Antwerp, 1 cs. (pt.), £6.; Brussels, 2 cs. (pt.), £46.

POTASSIUM CHLORIDE—

Demerara (F.), 10 c., £56.; Durban (F.), 5 c., £28.; Delagoa Bay, 2 t., £196.; Singapore, 3 cs., £16.

POTASSIUM CITRATE—

Melbourne, 1 cs., £14.; Wellington, 1 cs. (pt.), £8.

POTASSIUM CYANIDE—

Buenos Ayres, 4 cs., £58.; Penang, 6 cs., £350.; Singapore, 2 cs., £75.

POTASSIUM HYPO—

Montreal, 1 cs., £35.

POTASSIUM IODIDE—

Auckland, 1 cs. (pt.), £22.; Cape Town, 3 cs. (pt.), £39.; Durban, (F.), 2 cs. (pt.), £40.; Durban, 1 cs., £42.; Genoa, 2 cs. (pt.), £39.; Helsingfors (F.), 1 cs. (pt.), £78.; Lisbon, 1 cs. (pt.), £8.; Rosario, 2 cs., £80.; Shanghai, 1 cs., £81.; Wellington, 2 cs., £159.

POTASSIUM PERMANGANATE—

Rio de Janeiro, 1 cs. (pt.), £9.

POTASSIUM PRUSSATE—

Antwerp, 1 ck., £34.; Brussels, 1 ck., £28.

POTASSIUM SULPHOGUAICOLATE

Buenos Ayres (F.), 2 cs. (pt.), £75.; Rosario (F.), 1 cs. (pt.), £15.

PRUSSIAN BLUE—

Rio de Janeiro, 1 ck., £32.

PYROGALLIC ACID—

Hong Kong, 3 cs. (pt.), £9.; Lisbon (F.), 1 cs. (pt.), £5.

QUININE—

Buenos Ayres, 333 ozs.; Cape Town, 1,000 ozs.; Fremantle, 500 ozs.; Genoa, 882 ozs.

SALICYLIC ACID—

Auckland, 2 cs., £19.; C. Town, 1 cs., £6.; Genoa, 2 cs., £25.

SALT—

Auckland, 30 t.; Berbice, 9 c.; Durban, 3 t.; Mauritius, 1 t.; Monte Video, 2 t.; Napier, 105 t.; Porto Alegre, 1 t.; Valparaiso, 4 c.

SALTPETRE—

Auckland, 1 c., £6.; Bahia, 10 c., £29.; Bangkok, 2 c., £12.; Bordeaux, 118 t., (F.), £5,000.; Channel Islands, 5 t. (F.), £185.; Durban, 5 c., £17.; East London, 3 c., £9.; Galatz, 1 t., £68.; Ghent, 11 c., £30.; Lisbon, 1 t., £77.; New York, 100 t., (F.), £3,858.; Pernambuco, 1 t., £59.; Pernambuco, 50 t., £2,630.; Rio de Janeiro, 2 t. 9 c., £147.; Rio de Janeiro, 4 c. 28 c., £327.; Santander, 15 t., £720.; Santos, 2 c., £7.; Santos, 1 t. 19 c., £118.

SHEEP DIP—

Buenos Ayres, 30 t. 5 c., £1,623.; Durban, 18 c., £58.; Wellington, 16 c., £90.

SILVER NITRATE—

Buenos Ayres, 1 cs. (pt.), £33.

SOAP—

Antwerp, 213 t. 7 c.; Alexandria, 7 c.; Amsterdam, 3 t. 1 c.; Bangkok, 5 c.; Barbados, 1 c.; Batavia, 6 c.; Bilbao, 2 c.; Bombay, 1 t. 16 c.; Buenos Ayres, 6 c.; Calcutta, 1 t. 1 c.; Callao, 2 c.; Cape Town, 1 t. 7 c.; Chefoo, 1 c.; Christchurch, 1 c.; Cologne, 12 t. 15 c.; Colombo, 3 c.; Dunedin, 1 c.; Dominica, 1 c.; Dunedin, 1 c.; Dunkirk, 15 c.; East London, 2 c.; Fara, 1 c.; Genoa, 10 t. 5 c.; Hong Kong, 13 c.; Karachi, 8 c.; Kilindini, 1 c.; Lisbon, 4 c.; Madras, 19 c.; Malta, 84 t. 9 c.; Mazagan, 19 t. 8 c.; Marseilles, 2 c.; Montreal, 1 c.; Monte Video, 3 c.; New York, 12 c.; Paris, 27 t. 7 c.; Penang, 5 c.

SOAP—

Pernambuco, 6 c.; Piraeus, 4 t. 18 c.; Pt. Elizabeth, 3 c.; Pt. Moresby, 1 c.; Pt. Sudan, 1 c.; Punta Arenas, 1 t. 2 c.; Rabat, 2 c.; Rio de Janeiro, 5 c.; Rotterdam, 10 t. 17 c.; Salonika, 17 c.; Samarang, 8 c.; Singapore, 1 t. 11 c.; Smyrna, 5 c.; Shanghai, 2 t. 7 c.; Soerabaya, 12 c.; Stockholm, 39 t. 18 c.; Suez, 3 c.; Surinam, 1 t. 2 c.; Tangiers, 2 t. 10 c.; Tamatave, 27 t. 17 c.; Tripoli, 1 c.; Trinidad, 1 c.; Wellington, 2 t.; Zanzibar, 4 c.

SODA—

Cape Town, 1 t., £7.; Colombo, 1 t. 1 c., £12.

SODA ASH—

Genoa, 45 t., £315.

SODA CRYSTALS—

Calcutta, 15 c., £9.; Madras, 10 c., £5.; Punta Arenas, 1 t. 9 c., £17.

SODIUM BENZOATE—

Calcutta, 4 cs., £42.; Constantinople, 2 cs., £68.; Rotterdam, 40 cs., £4,953.; Santos (F.), 1 cs. (pt.), £16.

SODIUM BICARBONATE—

Allepi, 16 c., £16.; Bombay, 6 c., £24.; Buenos Ayres, 1 t., £42.; Calcutta, 1 c., £9.; Cape Town, 9 c., £18.; Durban, 10 c., £33.; Lisbon, 5 c., £6.; Madras, 9 c., £30.; Mollendo, 5 c., £10.; Panama, 3 c., £6.; Penang, 1 c., £5.; Rio Grande do Sul, 10 c., £7.; Rosario, 10 c., £14.; Talcahuano, 18 c., £9.; Trieste, 1 t., £23.

SODIUM BICROMATE—

Rotterdam, 10 t., £1,015.

SODIUM BISULPHITE—

Antwerp, 4 t. 12 c., £122.

SODIUM CARBONATE—

Hong Kong, 2 c., £5.

SODIUM CACODYLATE—

New York (F.), 2 cs., £475.

SODIUM GLYCEROPHOSPHATE—

Antwerp, 1 cs. (pt.), £7.

SODIUM HYDROSULPHITE—

Kobe, 3 cs., £50.

SODIUM HYPO—

East London, 1 t., £23.

SODIUM IODIDE—

Genoa, 2 cs. (pt.), £39.; Lisbon, 1 cs. (pt.), £11.

SODIUM NITRATE—

Calcutta, 2 c., £10.; Penang, 1 cs. (pt.), £12.

SODIUM PRUSSATE—

Boston, 5 t., £315.; New York, 80 t. 1 c., £5,967.

SODIUM SALICYLATE—

Melbourne, 5 kgs., £84.; Wellington, 1 cs. (pt.), £12.

SODIUM SULPHATE (GLAUBER

Galatz, 4 t., £90. SALTS)

SODIUM SULPHITE—

Hong Kong, 9 c., £7.

STEARINE—

Rotterdam, 10 c.

SULPHATE OF QUININE—

Cape Town, 700 ozs.

SULPHUR—

Aracaju, 10 c., £16.; Paris, 4 t., £120.

SULPHUR (FLOWERS)—

Lisbon, 10 brls., £24.; Piraeus, 10 brls., £17.

SULPHUR (ROLL)—

Lisbon, 5 brls., £11.

SULPHUR (SUBLIMED)—

Batavia, 2 c., £5.

SULPHURIC ACID—

Bangkok, 3 c., £16.; Beira, 8 t. 15 c., £140.; Constantinople, 16 c., £30.; Demerara, 7 t. 10 c., £137.; Pernambuco, 5 t., £500.; Trinidad, 2 t. 10 c., £46.

SULPHUROUS ACID—

Cape Town, 3 cs., £7.

SUPERPHOSPHATE—

Channel Islands, 168 t., £1,092.

TALLOW—

Genoa, 48 t.

TANNIC ACID—

Brussels (F.), 2 cks., £75.; Buenos Ayres (F.), 1 cs. (pt.), £28.; Constantinople (F.), 1 cs. (pt.), £53.; Lisbon (F.), 2 cs. (pt.), £25.; Rosario (F.), 1 cs. (pt.), £6.; Sao Paulo, 4 cs. (pt.), £71.

TAR—

Malmö, 3 cks., £100.

TARTARIC ACID—

Aden, 1 cs. (F.), £8.; Bombay, 2 t., £690.; Calcutta, 1 c. (F.), £12.; Calcutta, 3 c., £62.; Callao, 13 c., £283.; Delagoa Bay, 4 c. (F.), £83.; Durban, 5 c., £88.; Fremantle, 2 c., £39.; Hastings, N.Z., 1 cs. (F.), £6.; Hiogo, 5 t., £1,729.; Iquique, 2 c., £43.; Jamaica, 7 c., £140.; Karachi, 11 c. (F.), £239.; Limon, 1 c., £19.; Melbourne, 3 t., £863.; Mollendo, 1 cs., £7.; Montreal, 2 t. (F.), £672.; Montreal, 2 t., £620.; Osaka, 5 t., £1,729.; Penang, 1 c., £21.; Rio de Janeiro, 10 c., £195.; Santiago, Chile, 5 c., £110.; Sao Paulo, 1 ck., £10.; Sydney, 19 c., £273.; Thursday Island, 1 c., £18.

TERPINE HYDRATE—

Constantinople (F.), 3 cs., £45.

TITANIUM AND SODIUM**OXALATE—**

Auckland, 1 ck., £13.

VALERIANIC ACID—

Constantinople, 1 cs. (pt.), £9.

WAX—

Dunedin, 1 c.; Galatz, 4 t. 18 c.; Genoa, 1 t.; Helsingfors, 5 c.; Malmö, 6 c.

WHITE LEAD—

Auckland, £210.; Bordeaux, £300.; Calcutta, £466.; Cape Town, £128.; Durban, £14.; Lisbon, £43.; Novorissisk, £85.; Paris, £1,965.

ZINC CHLORIDE—

Amsterdam, 5 drms., £19.

MANCHESTER.

Week ending September 17.

ALUM—

Antwerp, 28 brls.

ALUMINA SULPHATE—

Antwerp, 349 bgs.

AMMONIUM CARBONATE—

Antwerp, 35 kgs.

BARIUM CHLORIDE—

Oporto, 4 cks.

BARIUM SULPHOCYANIDE—

New York, 8 cks.

BORAX—

Rotterdam, 85 bgs.

COAL PRODUCTS (otherwise undes.)

Bordeaux, £2,374.; Constantinople, £204.; Montreal, £184.; New York, 75 drms.; Rotterdam £281.

COAL PRODUCTS—

Carbolic Acid Crystals

Bordeaux, 26 drms.

Creosote Oil

Naples, 2,600 t.

DYESTUFFS (otherwise undescribed)

Bordeaux, 4 drms.

MAGNESIUM BISULPHATE—

Montreal, 10 cks.

PITCH—

Antwerp, 315 t.

SALT—

Quebec, 4,800 sks.

SHEEP DIP—

New York, 130 cs.

SOAP—

Antwerp, 18 cs., 300 pkgs.;

Rotterdam, 12 cs.

SODIUM BICARBONATE—

Antwerp, 145 bgs.; Rotterdam,

40 bgs.

SODIUM HYDROSULPHATE—

Antwerp, 50 bgs.; Rotterdam,

10 drms.

SODIUM PRUSSATE—

New York, 20 cks.

SODIUM TANNATE—

Montreal, 6 drms.

STEARINE—

Rotterdam, 16 bgs.

TANNIC ACID—

Rotterdam, 4 brls.

TARTARIC ACID CRYSTALS—

Montreal, 50 brls.

ZINC CHLORIDE—

Rotterdam, 41 cks.

MIDDLESBROUGH.

Week ending September 20.

AMMONIUM SULPHATE—

Kobe, 1,505 t., £29,051.; Yokohama, 947 t. 9 c., £18,241.

CAUSTIC SODA—

Kobe, 201 t., £3,800.

COAL PRODUCTS—

Pitch

Antwerp, 2,057 t. 14 c., £7,459.

DYESTUFFS & COAL PRODUCTS—

(otherwise undescribed)

Madras, 2 t. 9 c., £476.

MAGNESIA—

Canada, 7 t. 9 c., £476.

SALT—

Ahus, 219 t., £547.; Beira, 1 qr., £2.; Durban, 1 t. 12 c., £68.; Transvaal, 2 c., £48.

NEWCASTLE-ON-TYNE

Week ending September 20.

ANTIMONY

Rotterdam, 10 t.; Stockholm, 22 t.

BLEACHING POWDER—

Gothenburg, 23 t.; Rotterdam, 47 t. 14 c.

BORAX—

Rotterdam, 2 t.

CAUSTIC SODA—

Bergen, 6 c.; Gothenburg, 2 t.; Gefle, 10 t.

MAGNESIA—

Rotterdam, 9 c.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers) ...	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central. Manchester: 3980, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

EDITORIAL NOTICES.

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than Wednesday morning.

CURRENT TOPICS.

THE POSITION OF THE MERCHANT.

THE refusal of the Board of Trade to give the British Chemical Trade Association representation on the Dyes Licensing Sub-Committee, the correspondence concerning which we have already published, brings into prominence the whole question of the position of the merchant in the chemical trades, and the attitude of the large chemical manufacturers towards him. The reply of the Board of Trade to the British Chemical Trade Association that there is no need for it to be represented on the Dyes Licensing Sub-Committee raises one or two rather acute questions which cannot but be the better for being discussed. Incidentally, it may be pointed out that other trades have been and are experiencing much the same degree of hostility to the merchant that it is alleged is now being manifested in the chemical trades; but whether the conditions of the latter are so different from, say, the metal and hardware trades, as to lead to a different result, it is perhaps too early yet to say. The fact is that in these latter trades the merchants, after being severely handled during the war by Government departments, instigated by some of the large manufacturers, it is claimed, have to a large extent re-established their position as an essential factor in the trading organisation of the country. In treating this question of the utility or otherwise of the merchant on broad and impartial lines, it is only fair to say that the whole fabric of our export trade has in the past been built up by the brains and capital of the merchants. Conditions during the war were favourable—owing to the fact that, generally speaking, the Government were the only purchasers—for eliminating the merchant, and to a large extent that was done; but it cannot be said that the price to the consumer fell as a consequence of that elimination. There is, indeed, apt to be too much confusion between that common detestation, the middleman, and the merchant, but in fact there is nothing in common between the two. The middleman is the person who too often unnecessarily interposes between the merchant and the consumer, and takes few risks, and frequently has no capital; whereas the merchant is, in effect, the selling organisation for the manufacturer. The only alternative to him is the setting up by the manufacturer of a retail sales organisation; and as during the war, with the number of customers largely reduced, the partial elimination of the merchant had little effect

on prices, it is at least arguable that with a return to ordinary commercial conditions, and a large increase, necessarily, in the number of customers to be dealt with by the manufacturer, the cost of the necessary sales organisation which must be established if the merchant is to be entirely eliminated, will not result in prices being more favourable to the consumer than under the old régime. That question, however, we will leave the merchant and the manufacturer to fight out between them. If the large chemical manufacturers believe that they can carry on their trade better direct with the consumer, there is nothing in our commercial system which can give the merchant cause for complaint, provided the manufacturer has no extraneous aids to assist him which tell unfairly against the merchant. Every manufacturer is at liberty to carry on his business in the manner he thinks best, and the merchants would be the last to contest that argument. The bone of contention of the merchant, however, who has spent years developing a clientèle and has sunk all his capital for the general good of British trade, both here and abroad, as well as, naturally, for his own benefit, is that the manufacturers have been able to secure, if not direct, then indirect, assistance from the Government. The British Chemical Trade Association is so far recognised as representing the merchant class—it also has among its membership a certain number of the smaller manufacturers, who feel that their interests are liable to be swamped by membership of the Association of British Chemical Manufacturers—that its representative attends personally two or three times a week at the Department of Import Restrictions, and is in many cases able to get much quicker decisions with regard to applications for licences, for instance, than if the individual member of the Association took the question up direct with the Controller. That, of course, is not a privilege or facility special to this particular Association; it follows from the fact that Government Departments find it much more convenient to deal with representative bodies than with individuals, and the wisdom of that course has been demonstrated time after time during the past few years. It emphasises, incidentally, the necessity for all traders, be they merchants or manufacturers, to form their recognised trade association, and to endeavour to conduct its affairs on the strongest possible lines.

Having regard to the above facts, it is not surprising that the British Chemical Trade Association is taking a strong line of action on being refused representation on the Dyestuffs Licensing Sub-Committee, and the resentment is the more on account of the manner in which the decision was conveyed to them. The reasons for the application for membership are set forth in the correspondence; but an additional fact may be stated. It is known that in part payment of the indemnity Germany is sending to this country some £2,000,000. worth of dyestuffs. That will be dealt with by the Sub-Committee, which, put frankly, is alleged to consist of representatives of two dye-manufacturing concerns and two consuming combinations. Obviously, the merchants have a keen interest in the manner in which this large quantity of material is to be disposed of. Inquiries in the proper quarters have elicited the reply that no scheme has yet been arranged, but rumour has it that a scheme has, to say the least, been drafted, but the merchants have had no voice in it. Another matter which is causing discontent among the merchants is the routine which

an importer has to go through in order to get dyestuffs from abroad. He has to name his foreign house, the price paid for the material, and the person to whom he is going to sell. We do not suggest that in the interests of British manufacturers these regulations are too stringent, but the grievance is that a competing firm is acting, under the name of the "Central Importing Agency," as the Government's agents in connection with the importation of dyestuffs into the United Kingdom, and there is a natural disinclination to give away all this confidential business information to another firm in the trade, whatever its standing. In a sense, this is merely a perpetuation of the general war-licensing system, and merchants in all industries feel that they have been compelled to give away to Government officials who were often previously engaged in the particular trade, and have returned to it since, information which will by no means strengthen their position under normal conditions. It was hoped, however, that this method of procedure would be abandoned when Peace was signed, and there is more than one precedent for having foreign dyestuffs coming into the country under licence, distributed by a trade association, thus affording equal protection, facilities, and information to all members. If that were done we imagine the course would be to have a joint committee representing the Association of British Chemical Manufacturers and the British Chemical Trade Association. At the moment, of course, the further action which the British Chemical Trade Association contemplates taking, and has already set in motion, must be held up on account of the vital matters now occupying the attention of the Government, but we draw attention to the position because we do not wish to see the British chemical industry handicapped by internal disputes.

EXPORT CREDITS.

THE Board of Trade announce that the Government are prepared, through the Export Credits Department of the Board of Trade, 10, Basinghall Street, E.C. 2, to consider applications for advances up to 80 per cent. of the cost of the goods to the seller, including freight and insurance and the commission paid to the Department by the seller, in respect of exports to Finland, the Baltic Provinces (Latvia, Esthonia, and Lithuania), Poland, Czecho-Slovakia, Jugoslavia, and the areas in Russia to which the scheme for insurance against abnormal commercial risks applies.

The credits will be granted for such periods as the Department may determine in each case at the time of application for the advance. Advances will not be made for the export of raw materials, or of surplus Government stores, and preference will be given to the finance of goods where the larger part of the cost is due to manufacture in this country. All applications must be passed to the Department by the bankers of the seller, whose recommendation must be attached. Interest will be calculated at the rate of 1 per cent. above the Bank of England rate from time to time ruling, with a minimum of 6 per cent. per annum. Commission will be payable by the seller at the time the advance is taken; he may, however, include this commission in his invoice. The rates will not be less than 3 per cent. for the first year, 4 per cent. for the second year, 5 per cent. for the third year.

EFFICIENCY IN THE CHEMICAL INDUSTRY.

By J. H. WEST, A.C.G.I.; A.M.INST.C.E.

IT is a widely recognised fact that chemical manufacture in this country has been, and is still, very largely conducted on extremely inefficient lines, especially on the engineering side, and more particularly in the small works which represent so large a proportion of the whole industry. During the war British chemical manufacturers have been almost entirely free from external competition, they have obtained abnormally high prices for their goods, and they have had abundance of orders for special products required in connection with the war. The lean years are now upon us. Competition will again make itself felt, probably more severely than ever; wages and the cost of fuel and raw materials have risen enormously, and the chemical manufacturer is about to be faced with a tremendous problem in his efforts to place his goods on the market at competitive prices and yet make a profit. If he succeeds it can only be by attaining and keeping up the highest possible standard of efficiency in every department of his works, and more particularly on the engineering side, for it is there that large economies can be made by saving fuel, power, labour, and time.

This question of increasing the efficiency of chemical manufacture is one of the greatest national importance if we are to maintain and improve our position in the world's chemical markets; and it is an urgent one, for now is the time to make the improvement if it is to be of any value. It is no use waiting until the works are on the point of closing down through inability to make profits on the old lines. Everyone, from the Prime Minister downwards, is calling for increased production and a decrease in imports and in the consumption of fuel. Higher efficiency inevitably leads to increased output from the same plant, less consumption of fuel, and lower importation of raw materials per ton of product turned out.

The formation of the Chemical Engineering Group of the Society of Chemical Industry was a very hopeful step towards the recognition of the necessity for better efficiency in chemical manufacture, but it was only a preliminary step. What a magnificent opportunity now lies before this Group, not merely of justifying its existence, but of inaugurating an efficiency crusade which might well prove the very salvation of the industry! No other body is so well qualified to undertake this work; will it rise to the occasion? So far it has not shown much indication of doing so. It is a big undertaking, and one that requires to be handled on big, far-seeing lines, and above all it wants to be begun and pushed on with at once. In two or three years' time it may be too late.

Of the seven immediate aims of the Group put forward in February of this year, the last is far and away of greater importance than all the others. It reads as follows:—"Generally to promote by any means that may be available to the Group in regard to chemical industry in all its varied and associated lines—metallurgical and others—that increased productiveness and that higher commercial efficiency which have become essential not merely to enable this country to recover what we may have lost of foreign trade during the past

few years and to multiply and enlarge our markets overseas, but also to enable the country to sustain, and in due course reduce, the immense economic burden which the great war has laid upon us."

Now the problem of how to realise this increased productiveness and higher commercial efficiency may be divided into two parts, viz.: (1) The education of the chemical manufacturer as to the necessity for increased efficiency and the direct pecuniary advantages resulting from it; (2) the provision of men qualified to secure and maintain for the chemical manufacturer the increased efficiency which he wants, or will want when he has grasped the advantages to be derived therefrom.

The first question is really the fundamental basis of the whole problem. The British manufacturer is an exceedingly conservative individual, wedded to the methods he has used for years, which are most likely those his father used before him. He has a strong distrust of science and scientific methods, though the war has done a little to modify this prejudice, and above all he dislikes any outside interference with, or inquiry into, his system of manufacture. He likes to surround his works with an impenetrable wall, behind which his processes are carried out according to wonderful trade secrets; but if this wall keeps the secrets from passing out, it also prevents the light of progress and improvement from getting in.

It is notorious that the engineering side of the smaller works, at any rate, is almost invariably run on the most deplorable lines, the so-called engineer being generally a more or less superior fitter, with the natural result that no attention whatever is paid to fuel or power economy, or to manufacturing efficiency in any form. It is useless to say that the reason for this state of affairs is the lack of competent chemical engineers. Who can doubt that if there were an unlimited supply of fully trained and experienced chemical engineers available to-day, nine out of ten chemical manufacturers would refuse to employ them? No, the fault lies with the manufacturer's ignorance of what can be done by the application of scientific principles to the problems of manufacture, and his unwillingness to change his own methods, the inefficiency of which he does not in the least realise. Until this attitude can be changed it is quite useless training chemical engineers, reading papers on chemical engineering subjects, or endeavouring in any way to develop the science of chemical engineering. *The demand must come from the industry.*

VIGOROUS EFFICIENCY CAMPAIGN NECESSARY.

Here then is a great work for the Chemical Engineering Group to undertake. Let them go to the Executive of the Association of British Chemical Manufacturers and convince them of the necessity for a prompt, vigorous, and widespread efficiency campaign among the members of the Association in the first instance, and ultimately the whole body of British chemical manufacturers. Once the Association are convinced of the energetic determination of the Group to carry out the work, there is little doubt of their hearty co-operation and financial assistance.

Lectures and demonstrations should be arranged at all centres of chemical manufacture, and if possible at the chemical works themselves. The manufacturer must be convinced that he has far more to gain than to lose by bringing his problems into the open, and having them investigated by experts. An important feature of such lectures should be the explanation of the methods of testing the efficiency of boilers and plant, and of methods of ascertaining and analysing the various items which make up the cost of manufacture, for the average chemical manufacturer has but the vaguest notion of how his cost of production is made up, and it is precisely this ignorance which blinds him to the lack of efficiency in his works. The lectures should also give full information as to the results which have been obtained in actual works practice by the introduction of modern methods based on scientific principles, together with data showing the financial gain resulting therefrom.

First, then, get the manufacturer interested and alive to the fact that perhaps his methods could be improved upon, even if they are the result of many years' experience; next, show him how to find out what he really is doing from the efficiency point of view; then show him what improvement he might expect and be sure of getting with the best modern methods and appliances; and finally, when he has become a disciple of efficiency, persuade him, if possible, to give others the benefit of his experience. As regards the last point, it would be an enormous gain to the industry as a whole, and therefore to the country, if the manufacturer could be got to see that his deadly enemy is not his British competitor at all, but the foreign manufacturer in the same line. More co-operation and team work between British competitors in the same line is badly needed to assist in keeping foreign-made goods out of our home and overseas markets.

It will doubtless be argued that the campaign outlined above would cost a great deal, and that it would be impossible to find suitable lecturers and demonstrators. On the other hand, the Chemical Engineering Group has two great organisations behind it, viz., the parent Society of Chemical Industry, and the Association of British Chemical Manufacturers, both vitally interested in the prosperity of the British chemical industry, and it would be strange indeed if enough financial support could not be obtained to make a start, while the scheme should rapidly become self-supporting. As regards the provision of qualified men to carry on the campaign, there must surely be some enthusiasts available from among the present large and rapidly growing membership of the Group.

TRAINING CHEMICAL ENGINEERS.

So much for the first and most important part of the problem. The second part relates to the provision of properly qualified chemical engineers to advise and assist the manufacturers to attain and afterwards maintain the highest possible commercial efficiency in their works.

Paragraph 3 of the aims of the Chemical Engineering Group deals with the training of chemical engineers, and this question should be taken up without delay and put upon a proper footing, though, as has already been emphasised, it is useless training men until a demand arises from the industry for their services, for the existence of the trained men will not create the demand,

and men will not come forward to be trained until they are sure that there will be work for them to do at the end of their training. In any event, the organisation of training centres and courses of instruction must inevitably take a considerable time, so that under the most favourable circumstances it must be several years before a supply of trained men adequate to the needs of the industry can be available.

What, then, can be done in the meantime, probably the most critical period in the whole history of the industry? The only solution which appears practicable is that embodied in the following suggestion, viz., that the Chemical Engineering Group should at once establish a Consultative Committee of chemical engineers, whose services in an advisory capacity should be at the disposal of chemical manufacturers on the payment of standard fees, a portion of these fees going to the exchequer of the Group, and the remainder serving to remunerate the members of the Committee for their professional services. In this way the manufacturer would secure the assistance of experts in the various branches of chemical engineering, and he would have the assurance that he was obtaining unbiased advice, backed by the best knowledge and skill in the country.

At the present time there are, unfortunately, a number of persons about who call themselves chemical engineers on the strength of a few months spent in an explosives factory during the war, but who have had no training and practically no experience of the work. If the Chemical Engineering Group does not soon take in hand the question of the status of the chemical engineer, and set up a standard of qualifications to uphold that status, much harm will be done by such people. This question of the status and qualifications of the chemical engineer is a very urgent one, and the Group should make it one of the first matters to be dealt with, for the longer it is left the more difficult it will become, and the greater danger there will be of the manufacturer losing confidence in the chemical engineer owing to disappointments arising from dealing with incompetent men.

The collection and dissemination of information and data relating to chemical engineering, upon which great stress is laid in the Group's aims, is a very desirable undertaking, but it is of nothing like the same importance as the necessary machinery for linking up the manufacturer's interest with the activities of the Group, a point which seems to have been rather overlooked. It is no good waiting for the manufacturer to come to the Group—the Group must carry its campaign right into the works of the manufacturer, and now is the time to do it.

In conclusion, it should be stated that any criticisms of the Chemical Engineering Group contained in the above, and the suggestions made for the more vigorous and rapid extension of its sphere of usefulness, are put forward in the most friendly spirit, and are prompted solely by the conviction that the immediate needs of the chemical industry in this country call for the most energetic and speedy efforts to attain the utmost possible efficiency in manufacture.

WAGES IN THE CHEMICAL TRADES.—At the forthcoming periodical national wages revision in the chemical, soap, and candle and explosives industries Mr. James O'Grady, M.P., on behalf of the Federation of General Workers, will claim 10s. weekly increase for adults and 5s. for juniors, with proportionate advances for piece workers.

COMMERCIAL SYNTHESIS OF ORGANIC COMPOUNDS FROM ACETYLENE.*

By M. J. MARSHALL.

WHILE the use of acetylene as an illuminant has been well known for many years, its use in the commercial synthesis of organic chemical compounds is of more recent origin. However, the possible commercial utility of acetylene gas, on account of its very high chemical reactivity, has long been recognised by chemists, and attempts to utilise it in this manner date back probably just as far as its use as an illuminant.

This property of acetylene is due largely to the fact that it is a highly unsaturated compound of simple structure, having the formula $\text{CH}:\text{CH}$. Thus, not only does it react easily with other compounds, but at the same time the reaction products are quite simple in structure, thus making it possible to manufacture compounds which can be used as starting points in a large number of chemical syntheses. This high reactivity of acetylene makes the number of possible syntheses very large, but up to the present time only a comparatively small number of these reactions have been developed commercially.

The present article will not be confined merely to compounds which have been produced on a commercial scale, but patented processes will also be included, as a large number of these embryo processes are certain to be commercially successful in the future.

As was mentioned above, acetylene is an unsaturated compound, and can therefore form additional products with other compounds. At the same time, acetylene can be polymerised by heating to a sufficiently high temperature, decomposed into its elements by detonation under high pressure, or oxidised either directly or by electrolysis.

HYDRATION OF ACETYLENE.

The most important reaction at the present time, from a commercial and technical point of view, is the hydration of acetylene gas to form acetaldehyde, itself the source of many important synthetic compounds. This reaction proceeds according to the equation: $\text{C}_2\text{H}_2 + \text{H}_2\text{O} = \text{CH}_3\text{CHO}$, and takes place only in the presence of salts of mercury. The reaction was the subject of many patents, but it was not operated on a commercial scale till 1916, when the Shawinigan Water and Power Company, at the request of the British Government, successfully installed and operated the process with the aim of producing acetone for the manufacture of cordite. For this purpose a subsidiary company was formed, under the name of the Canadian Electro Products Company. The process of this company consists briefly of the following steps:

(1) The production of acetaldehyde from acetylene by passing acetylene gas through large kettles containing aqueous solutions of mercury salts. The aldehyde vapour is separated from the excess acetylene gas by refrigeration. This is then rectified to give a pure acetaldehyde of 99.9 per cent. purity.

(2) Oxidation of the aldehyde to acetic acid in the presence of appropriate catalysts. This is effected by passing air or oxygen through the aldehyde under pressure in the presence of catalysts, such as vanadium pentoxide, cerium oxide, manganese acetate, etc. The degree of conversion of the aldehyde to acetic acid is very high. After separating the excess aldehyde by rectifica-

tion, acetic acid, running 99.8 per cent. pure, can be obtained.

(3) Conversion of the acetic acid to acetone by passage through hot tubes over lime as a catalyst. This proceeds according to the equation: $2\text{CH}_3\text{COOH} = (\text{CH}_3)_2\text{CO} + \text{CO}_2 + \text{H}_2\text{O}$. This process was operated with reasonable success for about one year, the acetone being shipped to the British Government. However, towards the end of 1917 the manufacture of acetone was stopped, and acetic acid was produced and shipped to the British Government as before. It is not probable that the company will resume the manufacture of acetone, as this material can be produced more cheaply from commercial calcium acetate. It is understood that a plant of this type for the production of acetic acid has been in operation in Germany since 1916.

OTHER PRODUCTS FROM ACETALDEHYDE.

While, therefore, at the present time acetic acid is the main product manufactured from acetaldehyde on a commercial scale, there is no doubt that in the near future acetaldehyde will be the source of many other important organic compounds. This substance is even more wonderful than acetylene with respect to the great variety of reactions in which it can take part.

Paraldehyde.—Another product which has been manufactured for some time by the Canadian Electro Products Company is paraldehyde. This is manufactured by treating pure acetaldehyde with very small amounts of sulphuric acid. Considerable heat is evolved, and the aldehyde is converted to paraldehyde containing a certain amount of excess aldehyde. This excess aldehyde is finally removed by appropriate means, in order to obtain the pure paraldehyde.

Aldol.—While mineral acids tend to cause acetaldehyde to polymerise to paraldehyde; aqueous solutions of alkalis, on the other hand, cause the so-called aldol condensation, according to the equation: $2\text{CH}_3\text{CHO} = \text{CH}_3\text{CH}(\text{OH})\text{CH}_2\text{CHO}$. Thus N. Grunstein (U.S.P. 1,234,156, Br.P. 101,636, 1917) protects the production of aldol by treating acetaldehyde with calcium or strontium oxide, and a little water. On completion of the reaction this mixture is neutralised with acid, and the aldol is separated by distillation *in vacuo*. Aldol has been proposed for the preparation of cellulose acetate solvents. It is also used as a source of butadiene for the manufacture of synthetic rubber.

Ethyl Acetate.—If pure acetaldehyde is allowed to stand for about four hours in contact with about 5 per cent. of its weight of finely divided aluminium ethylate, about 90 per cent. is converted directly to ethyl acetate, according to the equation: $2\text{CH}_3\text{CHO} = \text{C}_2\text{H}_5\text{OOC}\cdot\text{CH}_3$. It should be noticed that this reaction involves the polymerisation of two molecules of acetaldehyde, as in the formation of aldol, although the resulting product is entirely different. This is one very good example of the great diversity of reactions in which acetaldehyde can take place.

From a technical point of view, this is a promising reaction, as the ethyl acetate produced is of very high quality, while the means necessary to effect the actual conversion are very simple. The great drawback at present, however, is the preparation of the aluminium ethylate. German patent No. 286,596 (1913) claims the preparation of this catalyst by the action of anhydrous alcohol on aluminium foil in the presence of a small amount of mercuric chloride. This action is not by any means rapid, and, after solution of the aluminium, it is

* Canadian Chemical Journal.

necessary to free the aluminium ethylate from the alcohol and mercuric salt. This last has also been the subject of several patents.

Acetal.—Acetal is often used instead of aldehyde for carrying out condensation reactions. It results from the combination of ethyl alcohol and acetaldehyde, according to the equation: $2C_2H_5OH + CH_3CHO = CH_3CH(OC_2H_5)_2$. It is prepared by mixing acetaldehyde and ethyl alcohol in the presence of a trace of hydrochloric acid, and an amount of calcium chloride equivalent to 10 per cent. of the weight of the liquid. Two layers form, which are separated, and the upper one repeatedly treated with fresh portions of calcium chloride till no more water separates. The liquid is then shaken with anhydrous sodium carbonate to remove traces of acid, filtered, and fractionally distilled.

Ethyl Alcohol.—Patents have been taken out for the preparation of ethyl alcohol from acetaldehyde by passing a mixture of acetaldehyde vapour and hydrogen over reduced nickel at temperatures below 180° . It is hardly probable, however, that alcohol can be produced as cheaply by this method as by the ordinary fermentation process.

Aldehyde Ammonia.—Aldehyde ammonia has recently come to the fore as an accelerator in the vulcanisation of rubber. This can be prepared by the direct addition of ammonia to aldehyde. The aldehyde is dissolved in anhydrous ether, and dry ammonia gas passed through. The aldehyde ammonia separates as a crystalline solid, which can be separated by filtration.

Chlorination Products of Aldehyde.—Acetaldehyde chlorinates very rapidly, with the evolution of much heat. A mixture of several products is obtained, which, so far, have not found any large commercial use. It is stated that acetyl chloride is formed in this way, although the amount so formed is not sufficiently large to be of technical importance. One of the products appears to be butyl chloral. On the whole, however, very little exact information is available so far concerning the exact nature of the reactions accompanying the chlorination of aldehyde.

Manufacture of Pure Nitrogen.—In the oxidation of aldehyde to acetic acid by means of air, considerable amounts of fairly pure atmospheric nitrogen are obtained. This by-product should certainly find a use in one of the several nitrogen fixation processes at present in existence.

PRODUCTS FROM ACETIC ACID.

From acetic acid a number of interesting products are obtained. Thus by passing chlorine gas into acetic acid in the presence of acetic anhydride, monochloroacetic acid is obtained. This product is of great importance in the manufacture of indigo.

Acetone.—If acetic acid vapour is passed over lime at a temperature of 450° C. practically all the acid is converted to acetone, with the liberation of carbon dioxide. In this case the lime acts as a catalyst only. As was mentioned before in connection with the description of the process of the Canadian Electro Products Company, this method of manufacturing acetone cannot compete financially with the ordinary method, consisting of the dry distillation of commercial calcium acetate. This is due to the high initial cost of the acetic acid compared with that of the acetate of lime.

Manufacture of Acetic Anhydride.—Acetic anhydride is an acetic-acid derivative of extreme technical im-

portance. It is used very largely in the manufacture of cellulose acetate and synthetic drugs. While cellulose acetate is a more valuable product than cellulose nitrate, nevertheless, at the present time the high cost of acetic anhydride limits its use considerably.

A method for the manufacture of acetic anhydride directly from acetaldehyde has been patented by Société L'Oyonnith (Fr. Pats. 420,346 (1910), 442,738 (1911)). The aldehyde is diluted with acetic anhydride and treated with chlorous anhydride, Cl_2O . The following reactions are stated to take place: $Cl_2O + 2CH_3CHO = (CH_3CO)_2O + 2HCl$. This process, therefore, supplies a means for the production of acetic anhydride directly from aldehyde, without the intermediate formation of acetic acid or an acetate.

Not only can acetylene act on free water to form acetaldehyde, but it can also form aldehyde by actually abstracting water from other chemical compounds, and thus acting as a dehydrating agent. Thus acetylene dehydrates acetic acid in the presence of mercury salts to form acetic anhydride and acetylates. The anhydride so formed immediately acetylates the aldehyde to form an ester of the ethylidene type, known as ethylidene diacetate. If this substance is heated, it tends to break up into aldehyde and acetic anhydride. This last reaction, therefore, opens a door for the manufacture of acetic anhydride directly from acetylene. Considerable attention had been devoted recently to the development of this process in Europe, but there seems to be a number of fundamental difficulties which have not yet been overcome.

The ordinary technical method of manufacturing acetic anhydride is by the action of chlorides of sulphur on sodium acetate. This process has been modified by Goldschmidt (U.S.P. 1,195,205 (1906)) by mixing sulphur with the sodium acetate and passing in chlorine. In this way the sulphur chloride is formed in contact with the substance on which it is to react. The first product of the reaction is acetyl chloride. This reacts with the excess of sodium acetate at a higher temperature—about 80° C.—to form acetic anhydride. The acetic anhydride is separated from the solid residue by distillation *in vacuo*.

Compounds of Acetylene With Other Substances.—It was found that acetylene in the presence of mercury salt could abstract water not only from acetic acid, but also from most compounds containing a hydroxyl group. G. Boiteau (Fr. Pat. 477,560 (1914)) claims the manufacture of entirely new compounds by the action of acetylene on alcohols. Also by dehydrating the product obtained from methyl alcohol and acetylene, he obtains butadiene. It would appear, therefore, that this series of reactions alone opens a very wide field to the utilisation of acetylene.

Compounds With Ammonia.—By passing a mixture of ammonia and acetic acid vapour over alumina at 500° C. acetonitrile is formed, according to the following equation: $CH_3COOH + NH_3 = CH_3CN + 2H_2O$. The yield is 85 per cent. of theory. The nitriles, as is well known, are important substances in organic syntheses.

Esters of Acetic Acid.—It is doubtful whether the manufacture of the commercial grades of esters from high-grade acetic acid would be able to compete with the method of manufacture direct from calcium acetate as now practised. It is possible that where an ester of the higher alcohols was required of a fair degree of purity, acetic acid could be economically used.

It is perfectly obvious that this single property possessed by acetylene—that of adding on water in the presence of mercury salts—is possessed of vast potential industrial importance. Thus, while at the present time the main application of this reaction on a large scale has resulted in the commercial production of acetic acid, no one can prophesy how far the uses of acetylene as a synthetic medium will extend.

This power of adding on water is only one of a large number of additional reactions which can take place between acetylene and other compounds. The remainder of this article will be devoted to a discussion of these reactions.

CHLORINATION PRODUCTS OF ACETYLENE.

Acetylene combines very violently with chlorine, forming addition compounds. Care must be taken in controlling the reaction, otherwise it is liable to proceed with explosive violence. The main product of this reaction appears to be tetrachlorethane, $C_2H_2Cl_4$, although a little dichlorethylene, $C_2H_2Cl_2$, is formed at the same time. The following equations represent approximately the course of the reaction:

Practically all patents taken out for the manufacture of tetrachlorethane by this method are for the purpose of preventing, as far as possible, the explosive combination of these gases. One of the most valuable methods appears to be that of Voigt (U.S.P. 908,051), who allows the reaction to take place in the interior of a porous mass made of sand, pulverised earthenware, infusorial earth, etc. The fine pores abstract the heat of reaction with sufficient speed to prevent explosion, while at the same time the apparatus is provided with a water jacket through which cold water is continually passed. The crude product obtained in this way is purified by fractional distillation.

Tetrachlorethane is a colourless, heavy, refractive liquid with a boiling point of $147.2^\circ C$. It is a very essential constituent of solvent mixtures for cellulose acetate dope. It is stated to give to cellulose acetate a resilient quality that no other solvent gives. In fact, tetrachlorethane has in cellulose acetate much the same function as camphor in nitro-cellulose. Tetrachlorethane is also the starting point in the manufacture of other chlorinated hydrocarbons.

Dichlorethylene, $C_2H_2Cl_2$.—This is prepared by suspending tetrachlorethane in water, and submitting it to the action of zinc dust. Considerable heat is evolved, and dichlorethylene distils off at $55^\circ C$. This substance is used as a solvent for cellulose acetate in conjunction with alcohol and tetrachlorethane.

Trichlorethylene.—This compound is also prepared from tetrachlorethane by abstracting one molecule of hydrochloric acid thus: $CHCl_2 \cdot CHCl_2 = CHCl : CCl_2 + HCl$. This is effected by treating tetrachlorethane with weak alkalis, or by passing the vapour of the same compound over surfaces of barium chloride or thorium oxide heated to 300° – $390^\circ C$., when hydrochloric acid is split off.

Trichlorethylene has a boiling point of $88^\circ C$., and is a very efficient fat solvent. It has the advantage over tetrachlorethane of not attacking metal vessels. Trichlorethylene is also important as the starting point of a whole series of valuable organic products. By acting on trichlorethylene with caustic soda, lime, and alcohol there is formed dichlorovinyl ether: $C_2HCl_3 + C_2H_5ONa = C_2HCl_2OC_2H_5 + NaCl$. This compound is wonderfully reactive. One very important property is its com-

bination with water in the presence of a trace of HCl at ordinary temperatures to form chloroacetic ester, thus: $C_2HCl_2OC_2H_5 + H_2O = C_2H_2ClOOC_2H_5 + HCl$. Chloroacetic ester is a compound which has been much used as a starting point for synthetic work. Chief among the products which can be synthesised in this way is indigo. The commercial manufacture of indigo, using acetylene as a starting point, is therefore possible.

Pentachlorethane and Hexachlorethane.—These compounds can also be prepared from tetrachlorethane by the acting on it with chlorine under the influence of actinic light. They are both used as constituents of solvent mixtures for cellulose acetate and cellulose nitrate.

ADDITION PRODUCTS OF ACETYLENE.

Hydrogen.—If acetylene and hydrogen are led over reduced nickel at a reasonably low temperature, ethane and a little ethylene are formed. It is claimed that ethylene alone is formed (Ger. Pat. 253,160) when the acetylene is reduced in the presence of platinum or palladium, together with iron, nickel, cobalt, silver, magnesium, zinc, cadmium, or aluminium.

Ethylene is the source of many important compounds. Through its chlorination product, ethylene glycol can be prepared. With concentrated sulphuric acid we can form ethyl sulphuric acid, which, on treating with water, gives alcohol. On the other hand, ethylene, when condensed with acetone, gives isoprene directly, which makes the synthesis of rubber possible by this means.

Nitrogen.—It has been stated that a mixture of nitrogen and acetylene, when exposed to an electric discharge or actinic light, forms hydrocyanic acid, according to the equation $C_2H_2 + N_2 = 2HCN$.

This points out a method of nitrogen fixation hitherto untried on a large scale, although the cost of the acetylene may make the method too costly for commercial use.

Products Formed at High Temperatures.—Although acetylene will not combine with water to form acetaldehyde below $100^\circ C$. in the absence of mercury salts, nevertheless, if the acetylene, mixed with steam, is passed through a tube heated to about 400° to $600^\circ C$. in the presence of appropriate catalysts, acetaldehyde is formed according to U.S.P. 1,244,901. In this particular case the catalyst recommended is molybdic acid on asbestos.

Under similar circumstances, in the presence of partly reduced bauxite, it is found (British Pat. 109,983, 1916) that acetylene can add on H_2S to form thiophene, or ammonia to form acetonitriles, picoline, and other pyridine bases. The study of reactions of this type should form a very fruitful field for future research.

The great drawback to work with acetylene at high temperatures is the tendency to form polymerisation products, which, together with any impurities in the gas, soon render the catalyst inactive, thus making it necessary to regenerate it quite frequently. At the same time it does not seem possible to obtain the products desired in any reasonable state of purity, a number of different substances being formed at the same time.

ACETYLENE BLACK AND HYDROGEN.

If acetylene is detonated under high pressure by means of the electric spark, a complete decomposition of the acetylene into its elements occurs, according to the equation $C_2H_2 = 2C + H_2$. This occurs at atmospheric pressure between 260° and $600^\circ C$. Many patents have been taken out covering this reaction. In a large number of cases provision is made for collecting the hydrogen produced. If oxides of carbon are introduced along with

the acetylene, these are reduced with the formation of water, no free hydrogen being produced in this case.

ELECTROLYTIC OXIDATION PRODUCTS OF ACETYLENE.

If acetylene is submitted to electrolytic oxidation in acid solution, in the presence of mercury salts, acetic acid is produced directly, according to the equation:

This method for the manufacture of acetic acid, so far, does not appear to have been utilised commercially, and it is very doubtful whether it can compete with the present synthetic process.

If electrolysis of the acetylene is allowed to take place in alkaline solution, on the other hand, salts of formic acid are produced. There is a possibility of reducing this formic acid to formaldehyde by reduction with hydrogen over reduced nickel. However, this process is not practicable at the present time, on account of the low yield of formaldehyde obtainable.

COMPOUNDS OF AROMATIC SERIES.

The polymerisation of acetylene to benzene by passage through a hot tube is a well-known reaction. However, as benzene can be produced much more cheaply as a by-product in the coal-distillation industry, this reaction is of no commercial significance.

Another possibility is the manufacture of phenol from acetylene by treating it with fuming sulphuric acid to obtain the sulphonic acid $(\text{C}_2\text{H}_2)_3(\text{SO}_4\text{H})_4$. Phenol is obtained from the potassium salt of this acid by treating it with potash and distilling the product. So far, this process has not been utilised on a commercial scale.

CONCLUSION.

Many of the reactions of acetylene have not been applied technically, and there is a very wide field in this direction for the utilisation of organic compounds which can only be manufactured at a high cost by other means. Even those processes for the utilisation of acetylene which have so far been patented are still mostly in an undeveloped state. It can therefore be seen that the future of acetylene, as the source of many important organic compounds, is particularly bright. In fact, acetylene should, in time, stand in the same technical relation to compounds of the aliphatic series as benzene at the present time stands in relation to compounds of the aromatic series. Looking further into the future, it can be seen that calcium carbide will come to be of ever-increasing importance to the chemical industry.

METALLURGICAL INDUSTRIES IN BELGIUM.

THE following is an abstract of a report issued by the Ministère de l'Industrie, du Travail, et du Ravitaillement of Belgium:—

Some of the coke ovens in Belgium remained in operation during the German occupation, and are in condition to continue work. Others which have been kept in good condition may resume operation within two or three months. Still others have not been kept in repair, and must undergo considerable overhauling, and will not be ready for resumption for six or seven months. The Germans destroyed only a small number of the ovens. From others they removed the distilling apparatus, but these may be used as ordinary ovens. Where considerable repairing or reconstruction of ovens is necessary fire-

brick will be needed. For ovens equipped with distilling apparatus there will be needed sulphuric acid for the manufacture of ammonium sulphate and heavy tar oils for the distillation of benzole. Some of the coke ovens, such as those at the Cockerill works, use a mixture of Belgian and foreign coal, the latter having a much larger content of volatile matter than the former. Plants producing composition coal fuels were generally spared by the Germans, who required them to furnish briquettes for use by the railroads.

The lead factory of the Dumont Brothers Co. at Sclaigheaux was almost entirely destroyed by the Germans. It is not known when this factory, which had been completely modernised before the war, can be rebuilt and put in working order. The Bleyberg plant, of little importance, remained completely inactive during the occupation. The Overpelt and Hoboken plants, belonging to companies largely owned by German capitalists, especially the latter plant, are only slightly injured, and can resume operation within a short time. A part of the equipment of the Baelen plant of the Vielle-Montagne Co. has been removed.

The zinc industry is situated in the Provinces of Liège, Limburg, and Antwerp. Aside from the Sclaigheaux plants, which have been destroyed for the most part, and the plant at Boom, whose equipment has been partly removed, the zinc plants have suffered relatively little, and may resume activity as soon as it is possible to procure the ore necessary. These ores came from foreign countries, especially Australia. The revival of the zinc industry is thus intimately connected with the activity of ocean, canal, and railway transportation.

INDIAN SESAMUM CROP.

THE first forecast of the Indian sesamum (til or jinjili) crop, 1919-20, issued by the Department of Statistics, India, is based upon reports received from eight provinces, which contain, on an average, 76 per cent. of the entire area under sesamum in British India. The returns in this forecast, however, exclude estimates for the United Provinces and for the late crop of Bengal.

A general comparison of the figures is made below with those for the corresponding period of last year. The total area so far reported is 1,520,000 acres, as against 1,291,000 acres (revised figure) for the same tracts at this date last year, or an increase of 18 per cent. Details of the area by provinces are as follows:

First Forecast, August.

Provinces.	1918-19.	1919-20.	Increase + or Decrease -
	Aores.	Aores.	Aores.
United Provinces*			
Madras	314,000	452,000	+ 138,000
Central Provinces and Berar	434,000	492,000	+ 58,000
Bombay and Sind (including Indian States)	161,000	260,000	+ 99,000
Bengal	169,000	167,000	- 2,000
Bihar and Orissa	138,000	83,000	- 55,000
Punjab	75,000	65,000	- 10,000
Ajmer-Merwara	—	1,000	+ 1,000
Total†	1,291,000	1,520,000	+ 229,000

*The estimated acreage is not reported until October in each year.

†Excluding the United Provinces.

‡As published in the October forecast (9,000 acres for early crop and 120,000 acres for late crop).

Seasonal conditions at sowing time have, on the whole, been favourable, except in parts of the United Provinces and Bengal, and the present condition of the crop is reported to be good.

SOME INORGANIC POISONS.

BY ALICE HAMILTON, M.D.*

ARSENIC.

OBSERVATIONS of industrial arsenical poisoning in the United States are scattered, and are not very detailed. Our most important arsenic industry is the manufacture of insecticides, Paris green (the acetoarsenite of copper), and lead arseniate. The two centres for this manufacture are Brooklyn and Chicago. While working for the New York State Division of Industrial Hygiene, Lester Roos examined fourteen men in two Paris-green factories and found three with inflamed eyes, two with ulcers, and four more with scars of old ulcers and furuncles, and two with marked anæmia. The Paris-green plants in Illinois employ a very fluctuating force of workmen, varying from about 12 in October to 561 in March. Few men remain in the work for long. It is one of the many industries in which a rapid labour turnover makes for the protection of the men against poisoning.

The reports of the Illinois Factory Inspection Department for the years 1912 to 1916 have several items on arsenical poisoning. These reports note that scrotal ulcers are pretty common among the men working in Paris green. Six cases of poisoning from Paris green and two from lead arseniate are noted one year; twenty cases another year from a force that varied between sixteen and 178. Two of these patients had ulceration; two, conjunctivitis and inflammation of throat and nose; the others, colic and constipation. I do not believe cases of poisoning from lead arseniate have ever been thoroughly enough worked up for one to say which element is the more important.

It is excessively hard to protect workers in Paris green. Two cases are on record of arsenical poisoning from the use of Paris green or arsenate of lead as a spray for fruit trees. The powder is very light and fluffy, and it has, so far, been impossible to carry out mechanical packing. No protection can be worn which makes the skin perspire, for perspiration only increases the danger of ulceration. Respirators do this by pressing on the skin and making it soft and thin. The best procedure seems to be to plug the nostrils lightly with cotton, to plug the ears in the same way, and to smear the face over with some bland ointment. A full shower bath ought to be taken at the end of work, and the work clothes should be clean each day.

Wholesale poisoning by the fumes of arseniuretted hydrogen has been reported several times, the victims being always persons confined in ill-ventilated parts of a ship, carrying in the hold a cargo of an alloy of iron and silicon—ferrosilicon. It is made by fusing together silicon (sand and quartz), coke, and iron in an electric furnace. Arsenic may be present in the quartz or in the iron, and in the presence of the coke it is converted into calcium arsenide, which in moist air is partly changed to arseniuretted hydrogen. If the silicon is present in the alloy in the proportion of less than 30 per cent. or more than 70 per cent., this does not occur; the dangerous points are between 40 per cent. and 60 per cent. silicon. Formerly we imported our ferrosilicon from Germany, but of late years we have made it at Niagara Falls. The

only instance of poisoning of this kind which can by any stretch be called American is that recounted by Kober as occurring on the *Vaderland* bound from Antwerp to New York with a cargo of ferrosilicon. Fifty steerage passengers came down with a mysterious sickness from which eleven died. The vessel was detained at quarantine under the suspicion of plague, but the discovery of the nature of the cargo explained the real cause of the sickness.

ANTIMONY.

The fact that the symptoms of antimonial poisoning are so like those of lead poisoning, makes it very hard to discover how great a part antimony plays in any case of occupational disease which occurs in a man exposed to both metals, as printers are. I could not find any evidence of antimonial poisoning in an examination of printers in 150 different shops, unless it was responsible for two bad cases of eczema of the hands and forearms of men working at the stereotype kettles.

The same difficulty is encountered in the second industry in which large quantities of antimony are used—the manufacture of rubber. Golden and crimson sulphides of antimony (really mixtures of the pentasulphide, the trisulphide, and the oxysulphide in different proportions) are used in great quantities and, so carelessly that one often sees men covered from head to foot with the reddish-brown powder. But these men, the compounders and those on the mixing mills, are also handling litharge and lead sulphate, and whatever symptoms they suffer from are much more likely to be caused by lead. In fact, toxicologists in general seem to think the sulphides of antimony quite harmless, only Kober believing that large quantities of the dust might cause poisoning in a workman. In order to throw some light on this question, the Bureau of Labour Statistics asked Professor A. J. Carlson, of the Physiological Department of the University of Chicago, to test the solubility of golden and crimson sulphides of antimony in human gastric juice. Dr. Carlson used commercial mixtures obtained from the B. F. Goodrich Co., of Akron. He found that about 8 per cent. of the antimony in the crimson and about 3 per cent. of the antimony in the golden sulphide were soluble in gastric juice, making it clear that these compounds are soluble in the human stomach. Dr. Carlson believes it to be probable that this solubility is sufficient to be a source of danger to men who are obliged to use these compounds in such a way as to expose them to a great deal of dust, or who handle food or tobacco when their hands are smeared with these sulphides of antimony.

Finally, antimony trisulphide is used in making fulminate caps, and, according to an expert of the Ordnance Department, some cases of possible antimonial poisoning were reported from that industry during the war, though it is impossible here also to separate the effects of the antimony from those of the fulminate. The symptoms enumerated by the ordnance expert—i.e., a local irritation of the skin and of the respiratory mucosa—might certainly be due to fulminate.

MERCURY.

Two quite extensive investigations into industrial mercurial poisoning have been published in the United States. The first investigation was published in 1912, and led to the discovery of ninety-four cases. Over 18

* Special Investigator of the U.S. Bureau of Labour Statistics, in a recent lecture at the Harvard Medical School.

per cent. of these came from thermometer makers. These people have to seal the glass tubes of the thermometers with heat. The glass often bursts and the mercury volatilises. In the Bausch and Lomb factory they have this well arranged. The workman slips his arms through openings in the furnace in which the tubes are sealed, and there is an exhaust to keep the air in the furnace from escaping.

Four of the patients from the Civic Federation list were making incandescent lamps. The risk comes here from the use of the Sprengel vacuum pumps, which may break and scatter mercury. These pumps are now being gradually replaced by rotary pumps, which are much less likely to break, but which have to be cleaned, and therefore there is still risk of poisoning. The pumps used for making Röntgen-ray tubes have even more mercury.

Mercurial poisoning in the making of fulminate is rare. I have heard of but one case that developed during the war, though, of course, there may have been more.

Another industry that involves the use of mercury amalgam is the MacArthur-Forrest cyanide process for the recovery of the precious metals. Mercury, according to Teleky, is sometimes used in the preliminary stage for this process, to form an amalgam with the gold and silver. Teleky has heard of no mercurial poisoning in this field, but of course we know that pretty widespread poisoning can go on in some of our more remote industrial centres where all the medical work is in the hands of company physicians, without the world at large knowing of it. This problem would make an interesting subject of research.

But the most notorious mercury trade is the making of felt hats and the preparation of fur for felt hats. In 1914 Dr. Louis Harris, of the New York City Department of Health, made a thorough study of conditions in the furriers' and hat-making trades in that city, and examined for mercurial poisoning large numbers of the employees. The men in the hatters' fur trade treat rabbits' fur with mercuric nitrate, a process known as carroting. Each person who subsequently handles the hairs is exposed to mercurial poisoning. Among 266 men in the New York shops, Harris found that 212 were exposed to mercurial poisoning in carroting the fur, in drying it in ovens, in cutting hair from the skins, and in sorting out the long hairs and packing the fine ones. Basing his diagnosis on evidence of gingivitis and violent muscular tremors, Harris decided that there were at least forty clear cases of mercurialism among these 212 men, and probably twenty more. No fewer than ninety-one had muscular tremors, and they were violent in seventeen.

It is interesting to note that the amounts of mercury used in felt-hat making are small, and that in the finished hat there is only 0.138 per cent. of mercury. Analysis of all the materials used, following them through the different stages, yielded as the highest content 0.17 per cent. The heat volatilising the small quantities of the mercury used in ill-ventilated rooms, is evidently largely responsible for the poisoning, and it is also evident that very small doses are enough to bring about serious results.

CARBON DISULPHIDE.

This is one of the trade poisons to the study of which Americans have made noteworthy contributions, though not in as great number as have the Germans, French, and

British. This is not because of neglect in the United States, but because we do not use carbon disulphide in industry as much as do foreign countries. Carbon disulphide is the substance which has made the rubber industry in Germany and France so notoriously dangerous, and though the British rubber industry seems to be carried on more like ours, still there are some quite shocking pictures of this kind of poisoning in British literature also.

In 1904, Jump and Cruice, of the University of Pennsylvania, published an interesting article on carbon-disulphide poisoning in artificial-silk workers. The history of one of these cases is so typical that it is worth quoting. The silk is made by treating cellulose first with caustic soda, then, in a closed tumbling vat, with carbon disulphide. At the completion of the reaction the carbon disulphide is largely, but not entirely, driven out with a blast of air. When the contents of the vat are dumped to be again treated with caustic soda, quite a little fume of carbon disulphide escapes. In cleaning these vats, too, the men are exposed to fumes. One of Jump and Cruice's patients said that when he went to work in the morning he felt exhilarated and jolly, though when the fumes were thick, as in cleaning a vat, he might be almost overcome and obliged to go out of doors. When he reached home in the evening he was morose and irritable, could eat nothing with pleasure because everything tasted of carbon disulphide. Presently he began to have severe headache, vertigo, weakness, first in the arms and then in the legs, until at last he could hardly climb stairs. He had muscular tremors, slight ataxia in the legs, a weakened grip, could not get up from his knees without help. His memory and his vision were impaired.

Hayhurst, in 1914, found only about 1 per cent. of the 30,000 rubber workers in Ohio exposed to carbon disulphide. This figure includes persons making rubber cement for the repair kits, to which carbon disulphide is commonly added.

PHOSPHORUS.

Phosphorus poisoning is much the most conspicuous and dreaded of the industrial poisons, and has caused more agitation, first for control and later for abolition, than all the others put together. Yet phosphorus does not affect more than a small proportion of persons exposed to it, and its mortality is only 15 to 20 per cent. It is, however, exceedingly painful, and so disfiguring that everyone can see the effects. Moreover, the offensive character of the discharge makes life with the victim almost impossible. I remember Miss Jane Addams telling me that in 1888 she went to a great mass meeting in London to protest against conditions in the match industry, and that there were a number of girls with horribly deformed faces on the stage to show the audience just what the effect of phosphorus was. I often think that if lead poisoning did all of its work on the face we should have been rid of it long ago.

I think you probably all know how we got rid of white phosphorus—by the passage in 1912 of the Esch law, which placed a prohibitive tax on white phosphorus matches. In 1913 their importation became illegal, and in 1914 their export. At the same time the Diamond Match Co., which held the patents for the manufacture of sesquisulphide matches, threw open to the whole

country the use of the process, thus making it possible for all to use the safe methods.

So far as I know, white phosphorus is used now very little in American industry. We do make phosphor bronzes, and an analysis of these bronzes shows that they contain from 0.068 per cent. to 0.813 per cent. of phosphorus. No case of poisoning has been reported from this industry in America, but it is well to bear it in mind. Kaup found a case in Austria, and, though the proportion of phosphorus in the bronze the man was working with was only 0.76 per cent., yet enough phosphuretted hydrogen was given off to poison him.

Ferrosilicon may give off phosphuretted hydrogen as well as arseniuretted, as reported by Glaister at the International Congress for Industrial Hygiene in 1910. We used white phosphorus last summer in the making of an incendiary projectile. I heard of no trouble from its use in this way, and probably it was not continued long enough for any cases of poisoning to develop. Occasionally one is told of phosphorus in connection with the manufacture of fireworks, a purpose for which it seems to be used in Italy.

TRADE WITH CONTINENTAL COUNTRIES.

A PARLIAMENTARY Paper published this week sets forth the conditions under which trading is permissible with certain countries, and notes are given on trading conditions as affected by the raising of the blockade. The Paper states that it may be expected there will be a considerable demand in the late enemy countries for all kinds of goods, and as this market is now open to all the world, it is no part of the policy of the Government to discourage British traders from competing therein; it is, indeed, desirable that British traders should make every effort to secure a proper footing in Central Europe.

Any goods may be sent to Germany without licence except goods on lists A and B of prohibited exports. It is understood that at present the import of all goods into unoccupied Germany is subject to import licence, for which the German consignee has to make application to the competent authority in Berlin. Any goods may be imported from Germany and paid for without licence except goods whose importation from all foreign countries is prohibited. Other transactions of a commercial or financial nature with firms in Germany are permissible without further licence, provided they do not involve any of the following matters:—

1. The payment of money arising out of pre-war transactions.
2. The delivery of or dealing with property held in this country for persons in Germany since before the outbreak of war.
3. The transfer of securities by or on behalf of a person in Germany.
4. The allotment or transfer of securities issued by a company to or for the benefit of a German subject.
5. The transfer of any debt or other obligation due to a person in Germany.

With regard to the territories previously included in the Austro-Hungarian dominions the British regulations are the same as those set out in the case of Germany, except that List D applies in the case of exports to Austria and Jugo-Slavia.

Except that List D of prohibited exports applies to Turkey and Lists D and E to Bulgaria, the British regulations are the same for those countries as for Germany.

It is mentioned that it is no longer necessary to obtain certificates from importing associations in Norway, Sweden, Denmark, Holland, and Switzerland. Export licences are required only for goods on Lists A and B of prohibited exports. So far as British regulations are concerned there are no special restrictions on trade with Finland, Esthonia, Lettland, and Lithuania, but, as in the case of other foreign countries, export licences are required for goods on Lists A and B, and general prohibitions of imports apply to these as to other countries.

Consular certificates of origin and interest are no longer required for goods imported into this country, while declarations of ultimate destination and disclosure of names of consignees will no longer be required to be made in respect of exports from the United Kingdom, except in a limited number of cases.

LEVER BROS. AND PRICE'S PATENT CANDLE COMPANY.

IN a circular to the shareholders regarding the offer of Lord Leverhulme to acquire the shares of Price's Patent Candle Co., Ltd., with its associated concerns, the directors of the Candle Company state that Lord Leverhulme approached them at the beginning of August. Setting forth the terms of the provisional contract, they state that a full half-year's dividend on the Lever Brothers' shares will be paid on January 1 next, and the interim dividend on the Candle Company's shares already declared would be paid. After selling their shares in accordance with the offer, the income to be received is put at say:—5 per cent. interest on £40, the cash consideration, £2; 15 per cent. on 32 "A" Cumulative Preference Ordinary shares in Lever Brothers, Ltd., of £1 each, £4 16s.; giving a total annual income per original Candle share sold of £6 16s., as compared with the dividend and bonus of £2 17s. 6d. per share paid by the Candle Company in each of the past two years.

The directors recommend the shareholders to take advantage of this offer, which must be accepted not later than October 9, and state that should a quotation on the London Stock Exchange for the new Lever shares not be granted within six months from the date of the sale Lord Leverhulme will, on demand, re-purchase these Lever shares at the price of £2 per share, payable in eight equal instalments at intervals of three months. The purchase will be completed on or before November 8 next.

Price's Patent Candle Co., Ltd., will preserve its identity, and its old traditions will be maintained. It is proposed to retain the present directorate and management, but Lord Leverhulme has undertaken to compensate in respect of loss of office any director who may desire to retire.

The circular adds: The negotiations which have led to this offer are outside the ordinary duties of directors, and in the belief that the shareholders would desire to recognise these services rendered to them by the directors and the general manager, whose exceptional services in this transaction entitle him also to special consideration,

it is proposed that the shareholders should surrender for their benefit one of the thirty-two 15 per cent. "A" Cumulative Preferred Ordinary share per Candle share sold.

GLYCERINE MANUFACTURE BY THE FERMENTATION OF SUGAR.

IT has long been known that the ordinary alcoholic fermentation of sugar yields about 3 per cent. of glycerine, and the study of the fermentation has shown that the conditions favouring a rapid fermentation, by the selection of a suitable yeast and by feeding the yeast with nitrogenous compounds, also favour the production of glycerine. Under ordinary conditions there is little object in increasing the glycerine percentage; when the explosive industry found a valuable material in glycerine, the fermentation process received further attention, and some glycerine was, in fact, isolated from the distillery residue before the war. But the fermentation process for the manufacture of glycerine was not worked out until the blockade deprived Germany of the imports of fats. It was rumoured during the war that the protol of the Protol Company was a fermentation glycerine due to the researches of Lüdecke and Connstein. Particulars were not published, but they have recently been given by Connstein in the *Wochenschrift für Brauerei*.

It would appear that as many as 63 factories were at one time engaged in this glycerine manufacture, but that only a few persevered with it. Yet an output of 1,000 tons per month is spoken of. The first important fact established by Lüdecke was that to produce glycerine the fermentation should proceed in the presence of an alkali, and that sodium sulphite, a relatively inexpensive alkaline substance, answers very well. This sulphite has the advantage of not injuring the yeast, which is very sensitive to some chemicals. A solution of 1 kg. of sugar in 10 litres of water, to which 400 grammes of the sulphite are added, together with the usual food for the yeast, alkali phosphates and sulphates, was completely fermented by 100 grammes of yeast in a few days. Quantitatively the products were 20 per cent. and more of purified glycerine, 27 per cent. of alcohol, and 3 per cent. of aldehyde. There is, of course, always considerable evolution of carbon dioxide. In general the glycerine percentage rises with the amount of sulphite present, whilst the alcohol percentage decreases at a roughly corresponding rate. To separate these products the yeast is filtered off; the alcohol and aldehyde are recovered by distillation; most of the salts are precipitated by adding calcium chloride and sodium carbonate to the liquid, and are therefore partly recovered as well, and the glycerine is finally obtained by distillation. This latter distillation is not free of difficulties, as is the case also when glycerine is manufactured in the ordinary way by the decomposition of fats; the new process had other serious difficulties to overcome. On the other hand, it is said that any sugar, and also molasses, and any kind of yeast will do, and that the fermentation temperature has practically no influence; the yeast, though modified, can be again used.

These statements do not quite agree with the results of experiments which were started in the United States by J. R. Eoff, W. V. Linder, and G. F. Beyer, of the Internal Revenue Bureau, when information about the German process had leaked out. The American experimenters recommend pure cultures of *saccharomyces*

ellipsoidus (var. Steinberg), and 5 per cent. of sodium carbonate gradually to be added to the sugar solution fermented at a temperature of 30° or 32° C., and they are, on the whole, more restricted as to the conditions of the fermentation. They worked with Porto Rico molasses, known as "black strap," but their glycerine was not pure, and the financial chances of the process did not look favourable. The cost was not mentioned in the German publication; probably protol is merely a war industry. At the same time, in Australia and Fiji molasses are at present discharged into the sea, and a recovery of both the alcohol and glycerine would alter the aspect of the problem.—*Engineering*.

"BURGUNDY MIXTURE."

THE chemistry of "Burgundy mixture" is particularly important, because to give it the greatest efficiency it should possess a maximum fungicidal power and a minimum potentiality for injuring foliage. The reaction of sodium carbonate and copper sulphate solutions has been studied by Pickering and by Ravaz, but, according to a paper contributed to the *August Journal* of the Chemical Society by Messrs. Robert L. Mond and C. Heberlein, the problem is more complex than they considered. The latter authors have studied the reactions of copper sulphate with varying proportions of sodium carbonate and of sodium hydrogen carbonate; have determined the amount of absorbed sodium carbonate and the ratio of copper oxide to carbon dioxide in the various precipitates, and the amount of basic copper sulphate in the mixtures; and have studied the solvent action of carbon dioxide and the change of the colloidal precipitate to a crystalline form.

As the result of their experiments Messrs. Mond and Heberlein conclude that three distinct copper compounds are formed when sodium carbonate and copper sulphate solutions are mixed: (1) Insoluble hydrated basic copper carbonate (the bulk of the precipitate); (2) insoluble hydrated basic copper sulphate; and (3) soluble basic copper sulphate in the form of a hydrosol; the proportions of which vary with the conditions of precipitation. One molecule of copper sulphate is completely transformed by 0.93 molecule of sodium carbonate instead of one molecule theoretically necessary. In a 1 per cent. mixture of copper sulphate and sodium carbonate (in the proportion 1:0.93 mol.) made at 15°, 9.6 per cent. of the copper is present as soluble basic sulphate, the basic carbonate contains copper oxide and carbon dioxide in the ratio 2.2:1, the insoluble basic sulphate contains copper oxide and sulphur trioxide in the ratio 15:1, the precipitate contains absorbed sodium carbonate in the proportion of 1 part to 74 of copper oxide, and 52.4 per cent. of the carbon dioxide is evolved. At higher temperatures more carbon dioxide is evolved, all being expelled on boiling.

The amount of basic sulphate formed decreases as the proportion of sodium carbonate increases, the proportion in solution (but not that of the basic carbonate) increasing with the amount of free carbon dioxide. At first the precipitate is wholly colloidal, but eventually it becomes crystalline, the colloidal condition apparently being conditional on the absorbed sodium carbonate. The transformation is accelerated by free copper sulphate, carbon dioxide, or sodium hydrogen carbonate, but retarded by sodium carbonate or 0.02 per cent. of glue.

ITEMS OF INTEREST.

PERSONAL.—Mr. J. S. W. Boyle has been appointed lecturer and assistant in chemistry in University College, Dundee, in succession to Dr. J. K. Wood.

HYDROGEN PEROXIDE MANUFACTURE IN NATAL.—Messrs. Kynoch, Ltd., of Umbogintwini, Natal, have recently erected an experimental plant for the production of hydrogen peroxide. The barium peroxide method was employed, the basic raw materials being South African barytes and locally produced sulphuric acid.

UNITED STATES PRODUCTION OF RADIUM.—The total production of radium in the United States up to the close of 1918 has been estimated at approximately 55 grammes, which is understood to be more than half of all the radium the world has produced. From recent survey work it is concluded that the carnotite of Colorado and Utah may yield at least 500 grammes.

ZINC AND ZINC DUST PRICES.—Zinc dust continues scarce, and the demand is brisk owing to the late arrival of Australian supplies. The price remains at £68. to £70. per ton, c.i.f. United Kingdom, for Australian high-grade (88-92%) metallic zinc. Australian electrolytic zinc (99.95% purity) is unchanged at £42. per ton, f.o.b. Australia, for direct shipment to New Zealand, India, South Africa, and the Far East.

NORWEGIAN COPPER MINES CLOSED.—The Sulitelma Copper Mines in Norway are confronted with the necessity of suspending operations, at least for the present time, owing to the falling prices of copper and the high cost of production. The company has on hand this year's entire output and part of last years, making a total of 600,000 tons; the number of workmen at the mines, which are exploited by a Swedish concern, is about 750.

COLUMN APPARATUS FOR TECHNICAL WORKING WITH GASES.—W. Bormann describes in the *Zeit. für Ange. Chemie*, of May 20 last, various forms of the Kubierschky column apparatus for washing, boiling, purifying, absorbing, and distilling gases, and for the recovery of the solvents used. These apparatus were first described in 1915, and seem to have undergone considerable development since then, and to have found wide and varied applications. They act in general on the counter-current principle, but are made in various modifications to adapt them to their special purposes.

LEVER BROTHERS' NEW ACQUISITION.—It is stated that Messrs. Lever Bros., Ltd., Port Sunlight, have just acquired the entire whaling business and outfit of the Southern Whale Fishing Company, Ltd., of which Messrs. R. Irvin and Sons, of North Shields and Aberdeen, are the managing directors and principal owners. This is the only English firm engaged in the industry in the Southern seas. By this latest purchase, which is said to have cost £750,000., Lever Brothers acquire a first-hand source of supply for material necessary in soap manufacture, and also in the production of margarine, which they carry on at their new Gretna works.

NEW ISSUE.—An issue of 300,000 7 per cent. cumulative participating preference shares of £1. each (free of income tax up to 6s. in the £) has been made by the South African Carbide and By-Products Company, a company formed with a capital of £307,500., divided into 300,000 7 per cent. participating preference shares of £1. each and 150,000 ordinary shares of 1s. each, by the Chemico Electric Company, for the purpose of manufacturing calcium carbide and of extracting motor spirit, tar oil, and other by-products from coal and shale at Ballengeich Collieries, Natal, South Africa. The company will also manufacture ammonium sulphate.

SILICA REFRACTORIES.—In Technical Paper No. 116 of the United States Bureau of Standards, Donald W. Ross arrives at the conclusion that, to prevent spalling, bricks should be kept between 1,250° and 1,350° C. for a long time, and gradually be raised to higher temperatures subsequently. Continuing the work of C. N. Fenner and of Spotts McDowell, at the Geophysical Laboratory and the Bureau, Ross investigated the changes in volume, porosity, specific gravity, and crystal form of the raw materials and of the leading commercial brands of silica bricks. Impervious, highly metamorphosed quartzites of tightly interlocking grains seem to give better bricks than porous quartzites with rounded grains. The true specific gravity of a silica brick, he considers, is a direct measure of the degree to which the brick has been burned, and from gravity and porosity the subsequent expansion of the brick can roughly be predicted. Other investigators are, rather doubtful about this estimate.

MAGNESIUM SULPHATE DEVELOPMENT IN CANADA.—The natural deposits of magnesium sulphate in British Columbia have received vigorous exploitation during the summer. Both the Stewart-Calvert Company, at Clinton, B.C., and the Basque Chemical Production Company, at Basque, B.C., are shipping. Eastern Canadian agents of these companies, says the *Canadian Chemical Journal*, are showing some very pure natural samples, and quite recently the Basque Company commenced shipping car-load lots of natural salts, guaranteed U.S.P. and B.P. grade. If freight rates allow, and the natural product is found satisfactory to the trade, a very valuable British Columbia industry has been established.

GERMAN CHEMICALS.—The prices of chemicals in Germany, and more especially of those used in connection with the manufacture of leather, have risen enormously; this is partly the fault of the "Zentralen" or Central Offices, which (in order to cover their working expenses) have repeatedly increased their purchase prices by 50 per cent. to 60 per cent., and of late even by 100 per cent. Even this latter figure has lately been exceeded! In the case of certain chemicals it is, as a matter of fact, now absolutely impossible to fix any prices at all, as these vary within very wide limits according to buyers and sellers in different localities. In other States matters are similar, although perhaps prices are not being so shamelessly forced up by middlemen. In Germany 1 kilogram of soda is about 5 marks, as against from 8 to 10 pfennige in pre-war days. There seems little prospect so far of any improvement.—*Leather World*.

USE OF MERCURY IODIDES.—According to a contemporary, a research into the behaviour of certain double iodides of mercury and other metals has been carried out by Mr. H. T. Pinnock, in order to determine which of these compounds is most suitable for use as a visible indicator of overheating in bearings and machinery. The double iodide of silver and mercury, AgI HgI₂, is a pale lemon yellow powder at ordinary temperatures, but changes to a vivid carmine at 90° to 100° C., the change in both directions being fairly sharp. With copper mercuric iodide, Cu₂I₂HgI₂, the change from vivid scarlet vermillion to a chocolate brown takes place at 60° to 70° C. It was found that a mixture of the two, consisting of 85 per cent. of the copper salt and 15 per cent. of the silver salt, was more sensitive and gave an exceedingly sharp transition from vermillion to almost black at 60° to 70° C. For application to bearings, etc., these compounds are mixed with white shellac spirit varnish, or, for higher temperatures, a medium such as is used in aluminium paints for steam pipes, in the proportion of 100 grammes compound to 70cc. of medium. This paint is best applied as a bull's eye or band on a zinc-white background. After the paint is dry, it should be protected with a coat of colourless oil-proof varnish.

STIMULATING AMERICAN PRODUCTION OF TUNGSTEN ORES AND COMPOUNDS.—The following is the substance of a Bill (H.R.4437) which has passed the United States House of Representatives, and is now understood to be before the Senate "to provide revenue for the Government to promote the production of tungsten ores and manufactures thereof in the United States." The Bill provides that on and after the day following its passage as an Act the following rates of duty shall be levied, collected, and paid upon the articles named therein, when imported from any foreign country into the United States, or into any of its possessions: (1) Crude tungsten, ores, and concentrates, \$10. per unit of tungstic trioxide therein contained, a unit being defined as 1 per cent. of a short ton of 2,000 pounds—namely, 20 pounds of tungstic trioxide; (2) metallic tungsten, tungsten powder, ferro-tungsten (lump and pulverised), ferro-tungsten powder, commercial tungstic acid, calcium tungstate, sodium tungstate, and all other salts of tungsten and other manufactured materials containing tungsten, including high-speed tungsten steel, all alloy steels containing tungsten, and all other compounds containing tungsten not specifically provided for, \$1. per pound of tungsten contained therein. The Bill also provides that there shall be levied, assessed, and collected upon all tungsten ore and concentrates which have been imported, prior to the passage of the measure, from any foreign country and held or kept within the United States, when such ore has been purchased by the owner thereof at a price less than \$17. per unit of tungsten trioxide therein contained, a tax equal to the difference between the purchase price so paid by the owner and the price named above. The provisions of the measure are not to be deemed to repeal any tariff now existing upon any substances or materials mentioned therein.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

The stoppage of the railways has caused much inconvenience in the tinplate trade, but attention is being paid to the export side of the business, and delivery of boxes to the ships is being accomplished by motor vehicles. If the dispute is not settled in a few days the tinplate mills will have to cease operating owing to the shortage of fuel. The decision of the Joint Committee of the Industrial Council to grant 12½ per cent. to all sections of workmen apparently disposes of the prospect of any strike in this trade.

As regards the patent fuel trade, the position is not so serious, as at many of the factories there are stocks of small coal on hand sufficient to keep them going over several days. The works of the Pacific Patent Fuel Company, Ltd., Swansea, are now resuming operations after a stoppage of eighteen months owing to the factory being seriously damaged by fire. The export trade is still on the increase, some large cargoes leaving for Rouen, Bordeaux, and Antwerp.

The copper workers have had very little employment owing to the scarcity of ores. There has been a great reduction in the number of hands at all the factories.

Coke ovens were fully occupied, the call for coke and by-products being well maintained. The railway dispute will not seriously interfere with operations at the ovens, as there are good quantities of raw material readily accessible.

The spelter manufacturers are very busy, but in this business, as with the majority of other industries, the supplies of fuel are obtained by rail, and it is feared that should the railway dispute be prolonged the furnaces will have to be entirely closed down. A cargo of 3,350 tons of zinc ore has arrived from Carthage.

Lead ores are not arriving satisfactorily. One source of supply—viz., the Laxey mines in the Isle of Man—has been nearly cut off owing to the wages dispute at Laxey, and, judging from latest advices, it is questionable whether the mines will restart.

LEGAL INTELLIGENCE.

Carriage on Chemicals: Curious Dispute.

In the Bow County Court, on Friday, September 26, before Judge Graham, K.C., the Maryport and Carlisle Railway Company and the Midland Railway Company sued Messrs. Burrell and Company, chemical and paint manufacturers, of West Ferry Road, Milwall, to recover £27. 1s. 8d., being the carriage on two 400-bag consignments of barytes from Wighton, in Cumberland.

Mr. Cripps appeared for the plaintiffs, and explained that the consignment note said that the consignees were to pay the carriage. They were sent off by Mr. J. Kerwin Cockton, of the Potsgill Mines, on November 11 and 13, and delivery was taken on November 13, 14, and 15. Being a highly respectable firm, they were not asked to pay the carriage on delivery, and then when the account was sent in they stated they were not liable as they had purchased them from a firm named Rylands, free delivery into their works. So far as the plaintiffs were concerned, they had nothing to do with that, as their contract was that they carried them "consignees to pay."

Judge Graham: But that does not bind the consignee.

Mr. Cripps: Certainly.

Judge Graham: But why? Has the consignor the right to bind the consignees in this case?

Mr. Cripps: We cannot say. We have to place faith in the consignor. We accept them on the condition that the consignee pays the carriage.

Judge Graham: I cannot help what is in your mind; I have only to do with the right or no of the consignor to bind the consignee.

Wm. Fredk. Dawes, clerk to the Midland Railway Company at the Victoria Docks, proved the delivery of the goods.

The defendants at this stage said that they were prepared to pay the carriage all along if the company could prove that they had been properly advised that they were liable. Had they known, they might have even gone to the length of refusing to take delivery. They referred the company to Rylands on being asked for the carriage, but they refused to have anything to do with anyone but the consignees.

Mr. Dawes then proved from the postage-book that letters had been posted to the defendants on the dates when the goods were received, and pointed out that it was significant

that they took delivery at once, but could not have known they were there except for the advice.

The defendants denied receiving them, and said that at the time of the Armistice it had become the practice of the railway company to telephone through when goods arrived, and that was what happened on this occasion. Had they been asked for carriage on the 'phone, a cheque would have been sent, but nothing was asked for.

Judge Graham asked the defendants why they did not pay now that they had seen the documents, and defendants protested that they had only just seen the copies, and had never had the originals. They were willing to pay; but as they had been willing to do this all along on the production of the proof, they did not think they should have to pay the costs.

Judge Graham agreed to this, and gave a verdict for the plaintiffs, without costs.

REPORTS OF COMPANIES.

Lawes' Chemical Manure Company, Ltd.

The adjourned 45th and 46th ordinary general meetings and the 47th ordinary general meeting were held in London on Thursday, September 25, Mr. Edward G. Cubitt, J.P., presiding. The Chairman said that the available balance, after providing for depreciation and contingent fund, amounted to £30,929, out of which the directors recommended the payment of a dividend of 7 per cent. on the preference shares and the payment of a dividend of 10s. per share and a bonus of 2s. 6d. per share on the ordinary shares. Summarising important items for the three years, it would be seen that the debentures, which at the commencement of the period stood at £6,000., had been paid off, and, including the amounts allocated out of the previous year's figures, a total of £25,300 had been written off for depreciation. The company's investment in British Government stock and cash at bankers and in hand amounted to £39,902. With regard to the general position, they had had to meet requests for very substantial increases of pay to the workmen. Unfortunately, it had been necessary to contend with one or two sectional strikes on the part of small bodies of the men. As to the future, the general position in the country was so uncertain that it was impossible to give any definite forecast. The difficulty of getting adequate supplies of raw material had been very acute for some time past, and so far showed no signs of improvement. This was due to two main causes. The first was the reduced output of raw phosphates in North Africa, from which source the company had for many years drawn a large proportion of their supplies; also, the French Government were retaining a larger proportion for their own consumption. The second cause was the scarcity of tonnage to bring the necessary phosphates from America to fill the shortage. While serious complaints were being made of congestion at the ports by the importation of goods not immediately required, the fertiliser trade had not been able to induce the Shipping Controller to provide tonnage for raw phosphate, which in London, at any rate, would not increase the congestion, as delivery would be taken from the ship in the river direct into the manufacturers' premises. This curtailment was not only going to have a serious effect upon the home supplies of fertilisers for the coming season, but had prevented British manufacturers taking a share in the very large demand for export. The loss of the export trade had a doubly prejudicial effect; it reduced employment and had an adverse influence upon the national balance-sheet, and a golden opportunity was being lost.

Resolutions for the adoption of the accounts for the years ended June, 1917, 1918, and 1919 were unanimously approved.

John Lysaght, Ltd.

An extraordinary general meeting was held in London on Tuesday, at which resolutions were passed increasing the capital to £2,600,000., and agreeing to the distribution of a bonus of £4. per share by the capitalisation of £1,600,000. of undivided profits.

DIVIDENDS.

ANACONDA COPPER MINING COMPANY.—Dividend of \$1. per share. A year ago \$2. per share was paid.

BELLS UNITED ASBESTOS COMPANY, LTD.—Interim dividend of 1s. per share (10 per cent. per annum)

RECKITT AND SONS, LTD.—Interim dividend of 6d. per share on the £1. ordinary shares—the same as a year ago.

CORRESPONDENCE.

.. We do not hold ourselves responsible for the opinions expressed by our correspondents.

The Dyestuffs Licensing and Distribution Scheme.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—I am instructed by my committee to send you the enclosed copy of a petition to the Right Hon. D. Lloyd George, M.P., which is being organised by this Association.

After extensive correspondence (as published in your last issue), and having failed to obtain satisfaction from the Board of Trade, it has now been decided to take this step in the hope of obtaining the introduction of a system more acceptable to the trade generally.

Forms of the petition will be gladly supplied to members of the trade on application to this office.—Yours, etc.,

THE BRITISH CHEMICAL TRADE ASSOCIATION.

O. F. BROMFIELD, Asst. Sec.

80, Fenchurch Street, London, E.C. 3, September 27, 1919.

[Copy.]

To The Right Hon. D. Lloyd George, M.P.

Sir,—We, the undersigned, being manufacturers, merchants, and/or consumers of dyestuffs, beg respectfully to protest against the present constitution of the Licensing Sub-committee, and also against the appointment of Messrs. Fairclough, Dodd and Jones (under the name of the "Central Importing Agency") as the Government's agents in connection with the importation of dyestuffs into the United Kingdom.

Extreme dissatisfaction is felt by merchants, consumers, and manufacturers (outside Messrs. British Dyes, Ltd.) in regard to the Licensing Sub-committee, which, as at present constituted, directly represents two dye manufacturing concerns and two consuming combinations only. The merchant, the independent consumer, and the small manufacturer are not represented at all. It is submitted, therefore, that the Committee is ill-balanced and does not carry the confidence of the trade generally.

It is therefore requested:—

(1) That representation upon the Licensing Sub-committee shall be granted to representatives of the smaller manufacturers, of merchants, and of the independent consumers.

(2) That the so-called "Central Importing Agency" shall be abolished, and that if such an organisation is necessary at all, that the work should be done either by (a) a Government Department who have no trade interests, or (b) an association representing the trade as a whole, and which would afford equal protection, facilities, and information to all its members.

(3) That a deputation may be received to explain in greater detail the trade point of view on the matter referred to.

NEW COMPANIES

Greengate Colour Works, Ltd.—Private company. Capital £2,000., £1. shares. Manufacturers of coal tar or other dyestuffs or colours of all kinds, chemicals, printers' inks, paints and writing inks, etc. Solicitors: Bingham, Hall and Ritchie, 29, Princess Street, Manchester.

Henzell Oil Company, Ltd.—Private company. Capital £50,000., £1. shares. Object: To take over the oil refinery business and works at Forth Banks, Northumberland, carried on by T. Henzell as the "Henzell Oil Company." Office: Forth Banks, Newcastle-on-Tyne.

Shawinigan, Ltd.—Private company. Capital £10,000., £1. shares. Manufacturers of and dealers in mineral, metallic, and electro chemical substances of all kinds, wholesale and retail manufacturing chemists, druggists, drysalts, oil and colourmen, etc. Registered office: 1, Tudor Street, E.C.

Spermolin, Ltd.—Private company. Capital £14,000., £1. shares. Object: To take over the business of oil merchants carried on by J. W. B. Winter and D. B. Winter, as the "Spermolin Core Company," at Black Swan Passage, Halifax, and the business of oil merchants carried on by the said J. W. B. Winter, as "Pollard and Winter," at Black Swan Passage, Halifax. Solicitors: Schofield and Son, Princess Street, Halifax.

Western Counties Basic Slag Company, Ltd.—Private company. Capital £50,000., £1. shares. Object: To take over the business of slag manufacturers carried on by the Western Counties Basic Slag Company at Neath, Glam. Solicitor: J. H. Glover, 60, Castle Street, Liverpool.

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Ammonia Soda Company, Ltd., Lostock Gralam.—Resolved August 28, confirmed September 15: That the company be wound up. C. M. Skinner, chartered accountant, of Jones Crowdsen and Youatt, 7, Norfolk Street, Manchester, liquidator. Meeting of creditors at liquidator's, September 30. Claims to liquidator by October 31.

British Waterproofing and Chemical Company, Ltd.—Meeting of creditors, 27, Brazenose Street, Manchester, September 29.

Peat, Coke, and Oil Syndicate, Ltd.—Claims to J. H. Glover, 6, Priory Place, Doncaster, liquidator, by October 31.

San Miguel Copper Mines, Ltd.—Meeting of creditors, Room No. 7, Salisbury House, E.C., October 2.

Wheal Bellan Tin Syndicate, Ltd.—Resolved August 27, confirmed September 19: That the company be wound up. F. J. Broomfield, 108, The Exchange, Mount Stuart Square, Cardiff, liquidator. Meeting of creditors at liquidator's, October 7, at 11 a.m.

DISSOLUTIONS OF PARTNERSHIP.

(Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.)

Sieber and Co. (Thos Schofield and Jno. Hy. Todd), Lee Mill, Shawclough, Rochdale, chemical manufacturers, drysalts, and tallow refiners. August 31. Debts by T. Schofield, who continues at Old Market Chambers, Yorkshire Street, Rochdale. (September 19.)

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W.1, whence, unless otherwise stated, further information may be obtained.

Australia.

A manufacturers' agent and broker in Brisbane desires to get into touch with United Kingdom manufacturers of oilmen's stores and chemicals, with a view to undertaking their representation in Queensland. (Reference No. 673.)

A Sydney import and export agent desires to get into touch with United Kingdom manufacturers of dyes for leather and woollens and lubricating oils in bulk, with a view to undertaking their representation for the whole of Australia. (Reference No. 676.)

Canada.

The following inquiry has been received at the Canadian Government Trade Commissioner's Office, Portland House, 73, Basinghall Street, E.C.2, whence further information may be obtained.

A manufacturers' agent and importer in Vancouver desires quotations upon the following: 150 tons soda ash for immediate shipment; 500 tons monthly salt cake (sodium sulphate); 200 tons monthly bleaching powder (available chlorine 35-37 per cent.). He also wishes to be placed in touch with United Kingdom manufacturers of industrial chemicals and kindred lines for use in the manufacture of paint, soap, and laundry supplies, and fertiliser materials, with a view to obtaining their representation.

British West Indies.

A firm of importers are desirous of representing in Trinidad British manufacturers of carbonic acid gas, Portland cement, manures, and fertilisers. (Reference No. 689.)

Egypt.

A commercial agency established in Alexandria wishes to come into touch with dealers in colours, varnishes, and chemical products. (Reference No. 691.)

A large firm of importers, with branches in Cairo and Alexandria, are open to act as exclusive sales agents, in Egypt. Articles which the firm would be willing to place on their market are aniline dyes, caustic soda, chemicals, paints, varnishes.

A firm in Cairo desire to receive catalogues, advertising matter, samples, and quotations of prices from United Kingdom manufacturers and exporters of paints, varnishes, and lubricating oils. (Reference No. 694.)

THE PATENT LIST.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Hydrogenating Oils. G. Martin, Manchester. British Patent, 129,461, of 1918.

In hydrogenating oils, fats, and waxes, the oil, etc., together with a catalyst, is run through heated conduits into which hydrogen is injected through perforated pipes, and the oil and hydrogen are arranged to circulate in opposite directions. Oil, mixed with catalyst, flows from a vessel *a* through conduits *i* heated by steam jackets *j*, and is returned by pipe *l*, pump *k*, and pipe *m* to the vessel *a*. Hydrogen, injected into each conduit by perforated pipes *o*, rises through the conduits and vessel *a*, and is circulated by a pump *e*, fresh supplies being introduced by a pump *g*. The oil may be led to the conduits *i* in parallel.

Acetaldehyde. O. Imray, London. (A communication from the Society of Chemical Industry in Basle, Basle, Switzerland.) British Patent, 130,138, of 1918.

In the manufacture of acetaldehyde by passing acetylene into dilute sulphuric acid containing mercury salts, the catalyst is continuously regenerated in the reaction liquid by electrolytic oxidation; oxygen carriers, such as ferrous, cerium, or chromium salts, may be added to assist the oxidation. The anode may be of platinum arranged at the bottom of the vessel so that the metallic mercury formed comes in contact therewith, or metallic mercury may be poured in at the start to form the catalyst by oxidation; or the anode may be suspended in the liquid and an auxiliary anode arranged in contact with the mercury; or the stirring device may act as anode. The cathode may be of copper contained in a diaphragm cell.

Cellulose Acetates. W. J. Stevenson, London. British Patent, 130,029, of 1917.

Bleached sulphite paper pulp is used to form cellulose acetate by treating with acetic acid, acetic anhydride, and a catalyst such as zinc chloride, nitric acid, or dimethyl sulphate.

Distilling Ammoniacal Liquors, Etc. W. Wyld, Menston, near Leeds. British Patent, 129,765, of 1918.

In apparatus for distilling and similarly treating ammoniacal or other liquors, comprising a number of troughs each having a serrated flange, over which the liquor flows, dipping into the next trough, while steam, etc., pass up between the troughs, the flanges are made adjustable. In the arrangement shown, the troughs *a*, *a'*, *a''* are arranged in sets across a vertical shaft, and are formed with turned-over lips to which the flanges *d* are attached by bolts passing through elongated slots in the flanges. The last trough *a''* of each set is provided with a fixed elongated flange *l* dipping into the first trough *a* of the next set.

Thorium Oxide and Salts. Lindsay Light Company, Chicago, U.S.A. British Patent, 129,624. Convention date, July 8, 1918.

A process for the separation of thorium compounds from material containing the same depends upon the solubility of thorium fluoride in a hot or cold solution of an alkali carbonate, ammonium carbonate, or a mixture of sodium car-

bonate and sodium bicarbonate, a soluble double carbonate being apparently produced. Starting with an acid or neutral solution of thorium, rare-earth metals, iron, zirconium, and titanium—as obtained, for instance, from monazite sand,—hydrofluoric acid or a soluble fluoride is added to precipitate the thorium and rare-earth metals and to dissolve the precipitated zirconium, leaving the titanium and iron in solution. The filter-cake is now heated with the carbonate solution, when the thorium dissolves, leaving the bulk of the rare-earth metals and any phosphates present unattacked. The thorium is precipitated from the filtrate as the hydroxide, and the product purified in any known way.

Electrolysis. Q. Marino and C. Bowen, London. British Patent, 130,302, of 1918.

An electrolyte for depositing lead or antimony or an alloy of lead and antimony on steel or iron is prepared by adding a solution of a lead or antimony salt such as the acetate or chloride, or a mixture of salts, to a solution of ammonium tartrate, then adding caustic soda or potash until the mixture is clear and then salicylic acid corresponding to about 5 per cent. of the weight of the lead or antimony salt. The anode consists of a plate of lead or lead-antimony alloy, or of carbon or platinum if pure antimony is to be deposited.

Chlorine and Aluminium Chloride. R. Welford, London. British Patent, 130,164, of 1918.

In the treatment of clay for the production of alumina according to Specification 118,312, the gases or vapours evolved when the clay is heated with hydrochloric acid and when the solution is evaporated to obtain chlorides or chlorides and oxides, are employed to make chlorine by known methods; for instance, by drying, mixing, with air or oxygen, and treating with a catalyst. Bleaching products such as bleaching-powder may be made from the chlorine.

Separating Potash and Soda Compounds. Distillates, Ltd., and G. G. Jarman, Kirkheaton, near Huddersfield. British Patent, 130,173, of 1918.

Potassium carbonate or potassium hydrate is separated from its mixture with sodium carbonate or sodium hydrate respectively, by treating a solution of the mixture with fatty oil or other saponifiable matter in quantity sufficient only to combine with all the soda. The mass is boiled to effect saponification, and evaporated sufficiently to cause the soda soap to separate on cooling. The soap may be broken up by the addition of an acid, and the fatty matter reused.

Cellulose Esters. P. E. C. Goissedet, Paris. British Patent, 130,277, of 1919.

Alkyl- or aryl-carbamates of cellulose are prepared by reacting upon cellulose or cellulose derivatives containing hydroxyl radicals with an aliphatic or aromatic isocyanic ester such as phenyl isocyanate. The reaction may be carried out in presence of tertiary bases, such as pyridine, or other solvents. The carbamates are precipitated on pouring the mixture into water, and may be washed with petrol ether.

Nitric Acid. A. T. Cocking and Kynoch, Ltd., Witton, Birmingham. British Patent, 130,038, of 1918.

Dilute nitric acid is treated with ammonia, and the solution of ammonium nitrate is evaporated to obtain crystals, which are dried and then heated with excess of strong sulphuric acid under reduced pressure to obtain strong nitric acid and acid ammonium sulphate. The residue is treated with ammonia to obtain neutral ammonium sulphate.

Destructive Distillation. F. M. Perkin, and Nitrogen Products and Carbide Company, London. British Patent, 128,660, of 1917.

The process of destructive distillation described in Specification 114,937 is modified to yield a greater percentage of aromatic by-products, more especially of benzene, by mixing acetylene with the gas which is passed through the retorts to assist in the carbonisation. The acetylene may comprise from 2.5-10 parts to 100 parts of the other component of the mixture which is passed into the retort, and the gas with which it is mixed may be the gas which is formed in the retorts after this has been stripped of its condensable portion, or producer gas, or other suitable gas.

Ammonia. R. C. Parsons, H. C. Jenkins, and C. I. Syndicate, London. British Patent, 130,069, of 1918.

In the catalytic preparation of ammonia from atmospheric nitrogen and hydrogen derived from the electrolysis of a solution of an alkali chloride, the hydrogen is passed first through filters containing coke or unglazed porcelain which is constantly moistened with water which has been boiled to free it from dissolved air and oxygen, and then through filters containing dry coke or porcelain, all the filters being provided with locks against the ingress of air. The nitrogen is obtained from the air by liquefaction and selective distillation. The alkali chloride solution is treated before electrolysis with barium chloride to remove sulphates, and is then boiled to expel air and oxygen. The solution is then electrolysed in cells such as described in Specifications 25,415/13, 22,867/14, and 104,600, the cathodes being made of nickel or iron containing no carbon.

Explosives. T. C. James, Aberystwyth, and J. I. M. Jones, and R. I. Lewis. British Patent, 130,357, of 1918.

Consists in making trinitrodiphenylamines by condensation of trinitrophenylmethylnitramines with primary amines, and in nitrating these condensation products to obtain such materials as hexanitrodiphenylamine and pentanitromethyl-diphenylamine for use as or in explosives.

Evaporators. J. A. Reavell, and Kestner Evaporator and Engineering Company, London. British Patent, 130,181, of 1918.

In an evaporator of the "climbing or falling film" type, extra tubes, D, D¹ are provided inside the evaporator casing A for pre-heating the liquid before it enters the evaporating tubes B. In the arrangement shown, the liquid enters into the lower header and the upper header is divided into two compartments and the lower into three a², a⁴, and a⁷. The heating tubes D enter into the compartments a², a⁴, and the evaporating tubes B enter the compartment a⁷. The heated liquid passes from the compartment a⁴ to the compartment a⁷ through a regulating valve a⁸, so that the requisite control of the flow of liquid from the heating to the evaporating tubes can be effected.

Nickel Salts. H. W. C. Annable, Egham, Surrey, and Nickel Concentration, Ltd., London. British Patent, 129,667, of 1917.

Nickel matte or sulphide or oxide nickel ore is heated with a chloride such as sodium chloride and, if there is a deficiency of sulphur, with a sulphiding-agent such as iron pyrites. The heating is effected in a neutral or non-oxidising atmosphere such as carbon dioxide, nitrogen, or steam, the temperature employed being 800-1000° C. The material is then oxidised in air at a temperature sufficient to decompose copper and iron sulphates but not nickel sulphate, and is finally treated with cold water, which dissolves the nickel sulphate. If copper is present in the residue, it is extracted by leaching with sulphuric acid.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Shale Distillation. G. W. Wallace, East St. Louis, Illinois, U.S.A. British Patent, 129,996. Convention date, February 8, 1918.

Shale and the like is distilled in a series of externally heated retorts, the oils and gases evolved being withdrawn through central perforated pipes so that they pass through the cooler material immediately on being formed. Retorts A, Fig. 1, are heated by gas from a producer D, and the burnt gases pass through a regenerator E. Beneath the retorts is a chamber B into which trucks C can be run to receive the material discharged. The retort A, Fig. 4, comprises a metal or like shell 10 with cover-plate 20 and base-plate 30. A perforated pipe F is mounted on the base-plate

30 to which is also removably attached a suction pipe 6. In operation, the oils and gases are drawn through the cooler material immediately they are formed and led away by the pipe 6^d. To discharge the retort, the pipe 6 is disconnected and swung clear, a tackle is hooked into an eye 12^a on a rod

12, nuts 9^a are stacked off and the plate 30 with the pipe F is lowered away. If steam treatment is desirable, the base-plate may carry a header from which perforated pipes project into the retort.

Acetic Acid. H. Dreyfus, Basle, Switzerland. British Patent, 130,035. Convention date, February 22, 1917.

Acetic acid is obtained by oxidation of liquid acetaldehyde at temperatures of 0 to 10° C. by air or oxygen at substantially atmospheric pressure, while bringing the gas and liquid into intimate contact by strong mechanical agitation. The process is effected without catalysts, or in presence of catalysts consisting of ferric oxide, ferric acetate, or mixtures thereof.

Distilling Glycerine. E. Barbet et Fils et Cie, Paris. British Patent, 129,649. Convention date, July 11, 1918.

In separating glycerine from the residual liquor from the distillation of alcohol, the liquors, after filtration and concentration in multiple-effect apparatus, are given a final concentration in an evaporator A connected through a froth-receiving vessel A' with a barometric condenser L. The concentrated liquor flows by pipe a' into a columnar still B in which each plate and the lower section are heated by superheated steam in coils V¹, and the outside walls are either constructed of non-conducting material or are formed with jackets for passage of superheated steam. The vapours pass to a condenser C, from which condensed glycerine flows through a separator c and barometric pipe n to a vessel N, and steam, etc., pass into the barometric condenser L. The residue from the still B passes down a steam-jacketed pipe H, into a heated trough K, and is discharged into cooled gutters m, in which it solidifies.

Alkali Sulphides. E. Bergve, Notodden, Norway. British Patent, 129,620. Convention date, July 8, 1918.

Alkali sulphides and "sulpho-silicates" are obtained by furnacing alkali-bearing minerals with pyrites and silicon, the latter being supplied preferably in the form of ferro-silicon. The ferro-silicon is stated to reduce and absorb any iron contained in the minerals, and to sink with it to

the bottom of the furnace. The upper portion of the smelt contains the alkali salts, together with aluminiferous material practically free from iron. Provision may be made for drawing off the material at different heights of the furnace.

Paints and Varnishes. Koppers Company, Pittsburg, U.S.A. British Patent, 129,264. Convention date, June 29, 1918.

A solvent or vehicle for paints or varnishes is prepared by subjecting crude solvent naphtha, such as results from the recovery of benzole from gas or tar, or which is obtained from the scrubbing of water gas and oil gas or other oil-bearing gases, or other liquids containing coumarone, indene, etc., or other bodies capable of polymerisation, to a polymerisation process, such as by heating under pressure in an autoclave. The undistilled product obtained directly from the autoclave

may be used in the manufacture of varnishes, paints, lacquers, etc., replacing, partially or wholly, the rosin, fossil resins, or vegetable oils ordinarily used, or the product may be distilled as described in Specification 123,806. As a specific example of the preparation of a coating material, 800lb. of bituminous pitch or coal tar pitch is heated to about 200° C., allowed to cool to about 150° C., and treated with 70gals. of the above-mentioned solvent. Thinners, driers, fillers, etc., such as turpentine, linseed oil, China wood oil, Venetian red, red lead, zinc oleate, manganese resinate, barium sulphate, etc., may be admixed with the solvent. In the case of low boiling-point naphthas it is advisable to cut out the fraction boiling below 135° C., and in the case of high boiling-point naphthas containing naphthalene, heavy paraffins, etc., the fraction boiling above 200° C. should be removed.

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London 90%, 2s.; North, 1s. 9d. to 1s. 10d.; 50%, 1s. 10d. to 1s. 11d.; North, 1s. 9d. to 1s. 10d. naked. Carboic acid, crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 9d. to 9½d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch, 77s. 6d. to 80s.; East Coast, 67s. 6d. to 75s., f.o.b.; West Coast, 62s. 6d. to 65s., f.a.s. Solvent naphtha, naked, London, 90-190%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-160%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthaline, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 5¾d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid, 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b., other ports. Sulphate of ammonia; home trade, September, £19. 10s. per ton.; October, £20. 10s., basis 24½%. Nitrate of soda, £22. to £22. 10s.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £103. to £103. 5s. cash; £101. 5s. to £101. 15s. three months; electrolytic, £110. to £120. Tin: Standard, £271. 10s. to £272. cash; £270. 10s. to £271. three months; Straits, £273.; English, £271. Lead: Soft foreign, £25. 12s. 6d.; English, £26. 15s. Spelter, £41. 10s.; hard, £28. to £30. Antimony, English regulus, 90%, £45. Aluminium £150. Nickel £205. delivered, packages extra. Quicksilver £23. 10s. to £24. Bismuth 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

Business is considerably affected by the railway strike, and delivery of goods practically at a standstill. Quotations generally for the principal products remain unaltered, and there is an active demand both for home and export trade. Bleaching powder continues quiet at £15. per ton, on rails. Refined bicarbonate of soda, bags, £8. per ton. Roasted saltcake firm at 60s. per ton, carriage paid. Chlorate of soda easy at 6d. per lb. Potash, 1s. per lb. Makers' quotations for bichromates are unchanged at 1s. 6d. and 11d. for potash and soda respectively. Recovered rock sulphur, £16. 10s., on rails. There is no sign of improvement in export demand for copper sulphate, and price is nominal at £41., f.o.b. Commercial hyposulphite of soda steady at £16. 10s. per ton. Phosphate of soda, £26. per ton. Concentrated sodium sulphide firmer at £24., drums, at maker's works. White powdered arsenic continues very scarce, and £60. quoted for small lots available. Yellow prussiate of potash 1s. 9d. per lb. Soda firm at 10d. per lb. Lead salts are quiet: English white, £83.; brown, £69. Nitrate, £56. per ton. Acetate of soda steady at £50., but in only small request. English brown and grey acetate of lime are steady at recent rates. Miscible wood naphtha scarce, and firm at 10s. 6d. per gallon. Nitrite of soda scarce on the spot, and price unaltered at £60. per ton. Green copperas is moving off better, but there is no improvement in price. Oxalic acid steady at 1s. 2½d. per lb., delivered.

SWANSEA MARKET REPORT.

THURSDAY.

Tinplate prices remain very strong, with a keen inquiry for export trade; a good volume of business is being done at 37s. to 37s. 3d. per standard box, f.o.b. There is a steadier feeling in the copper quotations, which include for the most part forward trading at about £100. 15s. per ton. Tin has been neglected. Spanish lead, £25. 12s. 6d. per ton; English, £26. 15s. Spelter, £41. 10s. per ton, f.o.b. Nitrate of soda steady at late prices. Seed oils scarce and firmly held at nominal prices. Palm oil easier: Lagos, £83.; softs, £81. 10s.; Benin, £80.; and hards, £79. Petroleum in strong demand at late prices, and very firm. Turpentine quiet at 129s. 6d. per cwt. Oxalic acid quiet at 1s. 2½d. per lb. Pitch dearer at 55s. 6d. per ton, ex ship.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

Business in chemicals has been disturbed by the railway strike, but the facilities for moving goods by motor-lorry and by boat on canal and river have admitted of a very fair movement of stock to towns within a reasonable range for such means of conveyance. Traders appear to be adapting themselves quickly and well to the new conditions, so that the dislocation by the stoppage of the railway services is not likely to be nearly as serious as was feared by many people. The motor vehicles will have saved the situation, and will have given manufacturers a much-needed element of independence in their ability to receive and to forward goods. Bleaching powder has been in fair request, and is £17. per ton free on rail or conveyance, in buyers' packages, with £15. to £18. per ton in buyers' packages being quoted for export lots. Chloride of calcium has been quiet, and is £8. to £11. per ton in casks, f.o.r. Caustic soda has been in fairly active inquiry, and is £24. per ton for 76%, £22. per ton for 70 to 72%, and £19. per ton for 60 to 62%. Nitrate of soda has been in moderate demand, and is £21. to £22. per ton. Saltcake has been in very fair request, and is £6. 10s. per ton in casks, f.o.b. Soda crystals have been in brisk demand, and are £5. 10s. per ton in 2cwt. bags, f.o.r. at works. Bicarbonate of soda has been rather freely inquired for, and is £7. 5s. to £10. per ton, according to terms of delivery. Borax continues in fairly active demand, with supplies for early delivery light. Higher prices are being asked, and may be given as: Ordinary, £45. per ton; powdered, £46. per ton, in bags. Ammonia alkali has been called for rather freely, and is now quoted at £6. 15s. per ton, f.o.r. at works. Hyposulphite has been quiet, and is £16. per ton for ordinary, and £21. per ton for pea crystals, in 1cwt. kegs. Sulphite of sodium has been but little in request, and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals, in 1cwt. kegs. Bichromate of soda has been in moderate demand, and is 9d. per lb. Phosphate of soda has been inactive, and is £25. per ton. Sulphide of sodium has met with but little inquiry, and is £20. per ton in casks, and £22. per ton in drums. Chlorate of potash has again been in fair request, and is 1s. to 1s. 2d. per lb. Permanganate of potash has been quieter, and is 3s. 3d. per lb. Sulphate of potash has been but little called for, and is £30. per ton. Carbonate of potash has been in very fair inquiry, but has been scarce. The price is £95. per ton for 80 to 85%. Caustic potash has been called for rather freely, and is £120. per ton. Nitrate of potash has been more inquired for, and is £60. per ton for refined, and £40. per ton for ordinary. Canadian

potashes have received but little attention. Montreal first quality are £200. to £220. per ton, and second quality £190. to £210. Bichromate of potash has been in fair request, and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been steadily called for, and is 1s. 9d. to 1s. 10d. per lb. Sal ammoniac has been in moderate request. Prices have been raised, and are now £90. per ton for lump, £80. per ton for seconds, and £5. per ton extra for ground. Sulphate of ammonia has been quiet, and is £20. 10s. per ton for October, £20. 15s. for November, £21. for December, £21. 7s. 6d. for January, 1920, £21. 15s. for February, and £22. per ton for March to May, 1920. Carbonate of ammonia has been quiet, and is 6½d. per lb. Muriate has been but little in request, and is £50. to £55. per ton, according to quality. Magnesia has been steadily called for. Carbonate is £2. 5s. per cwt., and sulphate, £10. to £16. per ton, according to grade. Alum has been in steady request, and has been in very sparse supply for early deliveries. It is £18. 10s. per ton for the home trade, and £18. 10s. to £19. 10s. per ton for export. Aluminoferric has been very quiet, and is £8. 10s. to £12. per ton, according to quality. Sulphate of alumina has had a moderate inquiry, and is £12. to £17. per ton, according to grade. Sulphur has been steadily called for, and English flowers are still scarce. They are £32. per ton. Roll is £28. per ton, and rock £22. per ton, in bags, f.o.r. Sicilian grades are: Flowers, £28. per ton; roll, £22. 10s. per ton; and rock, £17. 15s. per ton. Cream of tartar has moved but slowly, and is slightly dearer. It is from £11. 15s. to £12. per cwt. Tartaric acid has been in fair request, and is 3s. 1d. to 3s. 2d. per lb. Boracic acid has been rather more in request, and is £72. per ton for crystals and £74. per ton for powdered. Oxalic acid has been but little called for, and is 1s. 2d. to 1s. 3d. per lb.,

according to requirements for delivery. Citric acid has again been in fair request, and is 4s. 4d. per lb. White acetate of lead has been inactive, and is £85. per ton. Arsenic has been in moderate demand. White powdered is £58. to £60. per ton. Sulphate of copper has received but little attention, and is £41. to £42. per ton for home trade uses, and £42. to £43. per ton for export.

TYNE CHEMICAL REPORT.

TUESDAY

Market is without change, but the railway strike has entirely upset all arrangements, deliveries by rail being impossible. Export shipping business is also practically at a deadlock. Prices nominally, per ton, net: Bleaching powders, softs, £17.; caustic soda, 74-77%, £23. 5s.; do., 70%, £22.; do., 60%, £20.; recovered sulphur, 2cwt. bags, £23.; hypo-sulphite of soda, 5-7cwt. casks, £19.; do., 1cwt. kegs, £25.; sulphite of soda, 5-7cwt. casks, £12.; do., 1cwt. kegs, £20.; silicate of soda, 75° Tw., £9. 12s. 6d.; do., 100° Tw., £10.; do., 140° Tw., £10. 10s.; soda crystals, 2cwt. bags, £5. 10s.; sulphate of soda (saltcake), in bulk, £4.; pure white sulphate of alumina, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18.; do., defined concentrated, 60-62%, £25.; hydrate of barium, crystals, £56.

COALS.—The sudden railway strike has had the effect of bringing all business to a standstill, and should the strike last more than a few days it will lay the bulk of the collieries idle. Nominally, prices remain unchanged:—Best Northumbrian steam, 100s. per ton; do., seconds, 90s. to 95s.; Northumbrian small coals, 75s. to 80s.; do., seconds, 70s. to 75s.; best Durham gas coals, 80s. to 85s.; do., seconds, 65s. to 75s.; Durham bunker coals, 70s. to 80s.; do., seconds, 65s. to 70s.; foundry coke, 100s.; gas coke, 95s. to 100s.

IMPORTS OF CHEMICAL PRODUCTS

AT THE PRINCIPAL PORTS OF THE UNITED KINGDOM.

BRISTOL

Publication of Official Returns
Suspended.

GLASGOW.

Week ending September 27.

Alexandria, £8.; Bombay, 2 c., £29.; Bucharest, 19 c., £25.; Kobe, 15 t. 9 c., £815.; Oporto, 2 qrs., £3.; Piraeus, 10 c., £99.; Osaka, 19 t. 11 c., £1,643.

Creoline

Punta Arenas, £2.

Cresote

Colombo, 1 t. 12 c., £36.; Takubar, 190 t. 12 c., £2,365.

Cresylic Acid

Boston, 17 t. 13 c., £526.

Dyes

Dunedin, 5 c., £80.

Naphthalene

Aden, 13 t. 4 c., £190.; East London, 1 t. 7 c., £111.; Lagos, 2 c., £8.; Lisbon, 2 t. 1 c., £45.; Oporto, 10 c., £13.; Rosario, 1 c., £2.; Stamboul, 10 c., £24.

Pitch

Alexandria, 10 t., £50.

Tar

Cape Coast, 6 c., £2.; Saltpond, 250 galls., £9.; Stanley (Falklands), 1 t. 2 c., £27.; Punta Arenas, 1 t. 19 c., £63.

COPPER ACETATE—

Oporto, 22 lbs., £6.

COPPER SULPHATE—

Monte Video, 18 t. 7 c., £786.

CREAM OF TARTAR—

Aalcory, 2 c., £26.; Buenos Ayres, 2 c., £10.

DISINFECTANTS (otherwise undcs.)

Boston, 9 c., £16.; Bucharest, 3 t. 4 c., £75.; Calcutta, 6 t. 18 c., £261.; Cape Town, 1 t. 2 c., £56.; Gothenburg, 2 t. 18 c., £149.; Halifax, 4 c., £9.; Lagos, 2 c., £13.; Oporto, 4 c., £9.; Rangoon, 1 t. 8 c., £80.; Saltpond, 4 c., £5.; Victoria, B.C., 2 c., £4.

FERRO MANGANESE—

B'timore, 1,250 t.; Barcelona, 2 t.

FISH OIL—

Copenhagen, 32 brls.

GLUE—

Kobe, 300 bgs.

GLUE, SIZE, AND GELATINE—

Alexandria, 10 bgs.; Barcelona, 4 pkgs.; Bombay, 10 pkgs.; New York, 101 pkgs.; Oporto, 4 pkgs.; Shanghai, 95 bgs.

GLYCERINE—

Lisbon, 30 cs.

HEMATINE—

Calcutta, 2 c., £13.; Christiania, 3 c., £37.

MAGNESIUM CARBONATE—

Abo, 2 c., £5.

MAGNESIUM CHLORIDE—

Bangkok, 12 t. 10 c., £249.; Barcelona, 2 t., £40.; Bilbao, 10 t. 16 c., £135.; Bombay, 27 t. 13 c., £441.; Calcutta, 6 t. 7 c., £106.; Canton, 4 c., £5.; Hong Kong, 1 t. 15 c., £37.; Rangoon, 5 c., £5.

MAGNESIUM SULPHATE—

Cape Coast, 1 c., £8.

MURIATIC ACID—

Manaos, 1 c., £6.; Piraeus, 2 c., £13.

NICKEL SULPHATE—

Buenos Ayres, 9 c., £26.

NITRIC ACID—

Medellin, 2 qrs., £4.; Piraeus, 3 c., £18.; Zanzibar, 7 c., £10.

PHENIC ACID—

Oporto, 1 c., £8.

PHOSPHORUS—

Kobe, 4 t. 9 c., £866.; Medan, Deli, 25 lbs., £3.; Shanghai, 4 t. 10 c., £875.

PITCH—

Coronel, 2 t. 14 c., £67.; Punta Arenas, 9 c., £55.

POTASSIUM BICROMATE—

Barcelona, 3 t. 7 c., £542.; Constantinople, 1 t. 15 c., £309.; Oporto, 7 c., £58.; Piraeus, 5 c., £40.; Smyrna, 17 c., £125.

POTASSIUM BINOXALATE—

Abo, 2 c., £22.

POTASSIUM BROMIDE—

Antofagasta, 2 qrs., £20.

POTASSIUM CHLORATE—

Constantinople, 1 t., £118.; Kobe, 50 t., £3,294.; Mollendo, 2 c., £40.; Shanghai, 40 t., £2,630.

POTASSIUM IODIDE—

Opobo, 7 c., £783.

POTASSIUM NITRATE—

Teneriffe, 1 c., £15.

POTASSIUM PRUSSATE—

Oporto, 2 c., £27.

SALAMMONIAC—

Calcutta, 2 t. 5 c., £159.; Constantinople, 5 t., £353.; Funchal, 1 c., £5.; Manaos, 1 qt., £2.; New York, 3 t., £216.; Piraeus, 9 c., £35.; Rangoon, 1 t. 1 c., £75.

SALICYLIC ACID—

Copenhagen, 1 t., £300.; Piraeus, 4 c., £37.

SALT—

Buenos Ayres, 10 t.; Christiania, 100 t.; Lagos, 40 t.

SALTCAKE—

Drammen, 178 t.; Lisbon, 155 pkgs.

SALTPETRE—

Pernambuco, 30 t., £1,890.

SHEEP DIP—

Buenos Ayres, 30 t. 11 c., £1,048.; East London, 5 t. 14 c., £344.; Monte Video, 9 c., £17.; Punta Arenas, 109 t. 3 c., £5,113.; San Francisco, 5 t. 11 c., £236.

SODA CRYSTALS—

Algoa Bay, 6 kgs.; Casablanca, 20 kgs.; Gibraltar, 110 brls.; Oporto, 31 pkgs.; Salonica, 34 pkgs.; Smyrna, 15 drms., 5 pkgs.

SODIUM BICARBONATE—

Alexandria, 67 kgs.; Amsterdam, 73 bgs.; Constantinople, 440 cks.; Durban, 15 kgs.; Genoa, 213 pkgs.; Kobe, 1,814 pkgs.; La Libertad, 10 pkgs.; Lisbon, 220 pkgs.; Moji, 645 pkgs.; Oporto, 3 pkgs.; Stamboul, 450 bgs.; Yokohama, 1,614 pkgs.

SODIUM SILICATE—

Christiania, 30 cks.; Galatz, 64 cks.; Lisbon, 1,500 pkgs.; Montreal, 32 cks.; Monte Video, 100 cks.

SODIUM SULPHIDE—

Adelaide, 44 drms.; Genoa, 1,777 drms.

STEARINE—

Genoa, 28 cks.; Havre, 77 cs.; St. Nazaire, 260 bgs.

SULPHATE OF LIME—

Lisbon, 6 c., £10.

SULPHUR—

Colombo, 10 c., £17.; Copenhagen, 3 t., £127.

SULPHURIC ACID—

Montreal, 20 galls., £5.; Mombasa, 1 t. 4 c., £19.; Piraeus, 5 c., £13.; Suez, 274 t. 7 c., £4,521.; Valparaiso, 9 c., £17.; Zanzibar, 1 t. 10 c., £29.

TALLOW—

Genoa, 560 cks.

TAR (WOOD)—

Malacca, 6 t. 1 c., £73.

TARTARIC ACID—

Bombay, 1 t. 5 c., £425.; Montreal, 2 t., £649.

WAX—

Genoa, 32 bgs.

WHITE LEAD—

Lisbon, 2 pkgs.

ZINC CHLORIDE—

Alexandria, 9 t. 10 c., £499.; Batavia, 5 t., £267.; Bombay, 10 t. 10 c., £159.; Calcutta, 2 t. 7 c., £102.

ZINC SULPHATE—

Bombay, 15 c., £18.

LONDON.

Week ending September 24.

ACETIC ACID—

Brisbane, 9 cs., £29.; Dunedin, 15 cs., £45.; Ghent (F.), 6 brls., £80.; Galatz (F.), 18 cks., £300.; Genoa (F.), 103 pkgs., £1,516.; Helsingfors (F.) 18 cks., £232.; Pt. Sudan, 7 cs., £18.; Rangoon, 2 cs., £8.; Rio de Janeiro, 5 cs., £24.; Wanganui, 11 cs., £35.

ACETO SALICYLIC ACID—

Calcutta, 4 cs., £50.; Constantinople (F.), 1 cs., £46.; Mauritius, 1 cs., £29.; Samarang, 1 cs. (pt.), £20.; Singapore, 1 cs. (pt.), £6.; Stockholm, 6 cs., £140.; Shanghai, 1 cs. (pt.), £6.; Sydney, 3 cs., £92.

ALUM—

Batavia, 5 c., £7.; Singapore, 10 c., £14.; Trinidad, 4 c., £7.

ALUMINA SULPHATE—

Pernambuco, 5 cs., £10.; Rangoon, 10 c., £23.

AMMONIA—

Athens, 65 drms., £261.; Bombay, 10 cs., £20.; Boulogne, 42 drms., £390.; Buenos Ayres, 8 cs., £16.; Calcutta, 4 cs., £8.; Cape Town, 57 cs., £102.; Colombo, 19 pkgs., £42.; Demerara, 4 cs., £12.; Durban, 10 cs., £19.; Kilindini, 3 cs., £6.; Madeira, 6 drms., £8.; Paris, 85 drms., £941.; Pt. Elizabeth, 30 cs., £58.; Rio de Janeiro, 36 cs., £85.; Trinidad, 5 cs., £9.

AMMONIA (ANHYDROUS)—

Soerabaya, 1 cpl., £13.

AMMONIUM BROMIDE—

Bombay, 3 cs., £50.; Colombo, 1 cs. (pt.), £8.; Durban, 1 cs., £16.

AMMONIUM CARBONATE—

Batavia, 7 c., £40.; Buenos Ayres, 11 c., £42.; Calcutta, 1 t., £72.; Cape Town, 2 c., £10.; Cologne, 10 c., £31.; Demerara, 9 c., £40.; Durban, 5 c., £16.; Osaka, 5 t., £303.; Pernambuco, 4 c., £25.; Porto Alegre, 2 c., £12.; Rio de Janeiro, 2 t., £211.

AMMONIUM CHLORIDE—

Wellington, 2 cks., £8.

AMMONIUM CITRATE—

Calcutta, 3 cs., £50.

AMMONIUM IODIDE—

Calcutta, 1 cs. (pt.), £8.

AMMONIUM MURIATE—

Christchurch, 4 c., £13.; Italy, 1 c., £3.; Pernambuco, 1 c., £6.

AMMONIUM PHOSPHATE—

Piraeus, 4 cks., £26.

AMYL ACETATE—

Antwerp, 2 drms., £90.; Brussels, 1 dr., £108.; Hong Kong, 15 cs., £88.

ANTIMONY REGULUS—

Calcutta, £22.; Copenhagen, 4 t.

ANTIMONY SULPHATE—

Kobe, 14 cks., £470.; Montreal, 14 cks., £246.; Santos, 50 cks., £158.; Yokohama, 16 cks., £351.

ANTIMONY SULPHIDE—

Brussels, 14 cks., £145.

ARSENIC—

Helsingfors, 1 t. 3 c., £34.; Napier, 3 t., £135.; Pernambuco, 11 c., £98.; Santos, 1 t., £58.

BARIUM CHLORIDE—

Santos, 1 ck. (pt.), £8.

BARIUM CHROMATE—

Switzerland, 8 cks., £165.

BARIUM NITRATE—

Santos, 2 cks., £9.

BARIUM SULPHATE—

Christchurch, 1 ck., £7.; Oporto, 8 cks., £32.

BASIC SLAG—

Landnau, 49 t. 5 c., £172.; Medan, 100 t., £375.; Oporto, 49 t. 16 c., £192.

BEE'S WAX—

Cologne, 1 t. 5 c.

BENZOIC ACID—

Wellington, 1 kg., £15.

BIPHOSPHATE OF LIME—

New York, 3 cs., £10.

BISMUTH AND AMMONIUM CITRATE—

Auckland, 2 cs., £9.

BISMUTH CARBONATE—

Christchurch, 1 cs. (pt.), £22.

BISMUTH CITRATE—

Christchurch, 1 cs. (pt.), £5.

BISMUTH SUBGALLATE—

Dantzig, 1 cs., £126.

BISMUTH SUBNITRATE—

Colombo, 1 cs. (pt.), £10.; Dantzig, 1 cs., £147.

BISULPHITE OF LIME—

Pt. Elizabeth, 6 cs., £23.

BITUMINOUS SOLUTION—

Hong Kong, 140 drms., £332.

BORAX—

Albany, 10 c., £21.; Bangkok, 10 c., £21.; Calcutta, 2 c., £8.; Colombo, 5 c., £11.; Dantzig, 10 c., £26.; Fremantle, 6 c., £12.; Gothenburg, 9 t., £355.; Jamaica, 10 c., £31.; Paris, 20 t., £780.; Rio de Janeiro, 2 c., £8.

BORIC ACID—

Auckland, 4 c., £36.; Batavia, 3 c., £12.; Colombo, 4 c., £15.; Dantzig, 10 c., £45.; Dundee (F.), 4 c., £15.; East London, 1 c., £6.; Helsingfors, 5 c., £18.; Pernambuco, 1 c., £6.; Rio de Janeiro, 8 c., £49.; Tientsin, 2 c., £8.; Wellington, 6 c., £35.

CALCIUM CARBIDE—

Madras, 10 c., £12.; Rotterdam, 5 t., £119.

CALCIUM CHLORIDE—

Melilla, 2 t. 2 c., £250.

CALCIUM HYPOPHOSPHITE—

Genoa, 4 cs. (pt.), £76.; Gothenburg, 1 cs., £25.

CAMPHOR—

Buenos Ayres. a qty.

CARBON SULPHIDE—

Brussels, 3 cs. (pt.), £55.

CARNAUBA WAX—

Cologne, 17 c.; Rotterdam, 1 t.

CAUSTIC POTASH—

Perth, 1 cs., £15.

CAUSTIC SODA—

Auckland, 1 c., £6.; Rotterdam, 45 t., £855.

CERESINE WAX—

Cologne, 8 c.; Genoa, 1 t.; Melbourne, 5 t.; Rotterdam, 5 t. 18 c.; Salaverry, 15 c.

Auckland, 1 cs. (pt.), £5.; Colombo, 1 cs., £6.; Buenos Ayres, 1 cs. (pt.), £6.; Montreal, 4 cs., £221.; Soerabaya, 8 cs., £110.; Sydney, 1 cs. (pt.), £12.

IRON PERCHLORIDE—

Adelaide, 3 cs., £12.; Singapore, 4 cs., £45.

LACTIC ACID—

Helsingfors, 46 pkgs., £240.

LEAD ACETATE—

Bombay, 17 cks., 1 cs., £365. Calcutta, 3 kgs., £10.

LEAD IODIDE—

Brisbane, 1 cs. (pt.), £10.

LITHIUM BENZOATE—

Lisbon, 1 cs., £9.

MAGNESIA (CALCINED)—

Bahia, 1 cs., £21.; Porto Alegre, 1 cs. (pt.), £9.; Rio de Janeiro, 3 cs. (pt.), £50.; Sao Paulo, 4 cs., £55.

MAGNESIUM BENZOATE—

Pernambuco, 1 cs. (pt.), £5.

MAGNESIUM CARBONATE—

Helsingfors, 5 cs., £13.; Melbourne, 2 cs., £6.; Rio de Janeiro, 6 cs., £46.

MAGNESIUM CITRATE—

Barcelona, 5 cs., £60.; Malta, 1 cs., £7.

MAGNESIUM SULPHATE—

Albany, 5 c., £10.; Batavia, 10 c., £17.; Brisbane, 3 t. 12 c., £140.; Buenos Ayres, 3 c., £10.; Casablanca, 5 c., £10.; Fremantle, 2 t. 1 c., £62.; Invercargill, 19 c., £39.; Madras, 7 c., £20.; Montreal, 2 t. 10 c., £51.; Pernambuco, 12 c., £16.; Tangier, 10 c., £19.; Toronto, 1 t., £20.; Wellington, 15 c., £30.

MERCURY BICHLORIDE—

Paris, 4 cs., £300.

MERCURY CHLORATE—

Amsterdam, 1 cs. (pt.), £14.

MERCURY OXIDE—

Constantinople, 1 cs., £93.; Paris, 12 cs., £840.

METHYL SALICYLATE—

Cape Town (F.), 1 cs., £11.

MINERAL WAX—

Lisbon, 15 c.

MYRBANE OIL—

Antwerp, 22 drms., £908.

NICKEL SALTS—

Christchurch, 3 cs., £11.

NICKEL SULPHATE—

Kobe, 220 cs., £670.; Yokohama, 80 cs., £220.

NITRIC ACID—

Rangoon, 1 c., £14.

OXALIC ACID—

Rouen (F.), 4 cks., £150.; Soerabaya, 4 cs., £11.

PARAFFIN WAX—

Bordeaux, 5 t.; Oporto, 1 t.

PHOSPHORIC ACID—

Montreal, 16 pkgs., 2 cs., £341.; Naples, 1 cs., £15.; Paris, 40 cbs., £350.; Perth, 1 cs., £8.; Rio de Janeiro (F.), 1 pkg., £18.

PHOSPHORUS—

Athens, 2 cs., £31.

PHOSPHORUS (AMORPHOUS)—

Rio de Janeiro, 4 cs., £59.; San Francisco, 2 cs., £32.

PHOSPHORUS PENTACHLORIDE

Amsterdam, 3 cs., £29.

PLUMBAGO—

Calcutta, 3 t. 5 c.; Gothenburg, 1 t. 11 c.

POTASH—

Wellington, 1 dr., £6.

POTASSIUM ACETATE—

Calcutta, 1 cs. (pt.), £5.

POTASSIUM AND MANGANESE HYPOPHOSPHITE—

Genoa, 2 cs. (pt.), £19.

POTASSIUM BICARBONATE—

Auckland, 1 cs., £5.; Calcutta, 1 cs. (pt.), £8.

POTASSIUM BICROMATE—

Amsterdam, 1 cs. (pt.), £6.; Athens, 2 cks., £128.; Batavia, 2 kgs., £39.; San Francisco, 1 kg., £19.

POTASSIUM BROMIDE—

Calcutta, 1 cs. (pt.), £22.; Durban, 1 cs., £20.; Rio de Janeiro, 1 ck., £28.

POTASSIUM CARBONATE—

Canterbury, 1 cs., £5.; Paris (F.), 56 cs., £425.

POTASSIUM CHLORIDE—

Buenos Ayres, 2 cs., £26.; New York, 16 cs. (pt.), £17.

POTASSIUM CITRATE—

Auckland, 1 cs., £14.; Calcutta, 1 cs. (pt.), £7.; Colombo, 1 cs. (pt.), £14.

POTASSIUM CYANIDE—

Arica, 4 c., £55.; Colombo, 1 cs., £6.; Wellington, 1 cs., £8.

POTASSIUM HYDROXIDE—

New York, 16 cs. (pt.), £11.

POTASSIUM IODIDE—

Calcutta, 1 ck. (pt.), £87.; Gothenburg, 1 c., £170.; Jamaica, 1 cs. (pt.), £35.; Mauritius, 1 cs. (pt.), £9.; Mombasa, 1 cs. (pt.), £12.; Naples, 2 cs., £85.; Penang, 2 cs. (pt.), £48.

POTASSIUM METABISULPHITE—

Oporto, 2 cs., £18.; Piraeus, 20 cks., £192.

POTASSIUM OXALATE—

Rio de Janeiro, 1 cs., £17.

POTASSIUM PERMANGANATE—

Calcutta, 2 cs., £40.; Wellington (F.), 1 cs. (pt.), £5.

POTASSIUM SULPHATE—

New York, 16 cs. (pt.), £6.; Rio de Janeiro, 1 ck., £38.

POTASSIUM TARTRATE—

Gothenburg, 2 kgs., £17.

PRUSSIAN BLUE—

Singapore, 5 cks., £87.

- QUININE**—
Bombay, 100 ozs.
- ROCHELLE SALTS**—
Bermuda, 4 cs. (pt.), £7.
- SALICYLIC ACID**—
Durban, 1 kg., £10.; Helsingfors, 2 cks., £20.; Napier, 1 cs., £17.; Penang, 1 cs. (pt.), £6.; Rangoon, 2 cs., £15.; Singapore, 2 cs., £21.
- SALT**—
Boulogne, £115.; Brisbane, 4 t.; Colombo, 4 t.
- SALTPETRE**—
Bordeaux (F.), 118 t., £5,000.; Bahia, 14 c., £52.; Beira, 2 c., £7.; Bermuda, 1 c., £7.; Boulogne, 5 t., £325.; Cape Town, 10 c., £30.; Colombo, 3 c., £17.; Canterbury, 5 c., £17.; Calcutta, 1 c., £9.; Lisbon, 1 t. 16 c., £95.; Melbourne, 5 t. 2 c., £255.; Oporto, 9 t. 13 c., £517.; New York (F.), 50 t., £1,929.; Pernambuco, 12 t. 14 c., £803.; Rio de Janeiro, 9 c., £29.; Rotterdam, 2 t. 1 c., £107.; Santos, 20 t., £1,200.; Sao Paulo, 1 t., £59.; Tientsin, 1 c., £6.; Treport, 1 t. 6 c., £75.; Trinidad, 2 c., £7.; Wellington, 5 c., £15.
- SHEEP DIP**—
Buenos Ayres, 56 t. 5 c., £2,245.; Pt. Elizabeth, 5 t. 14 c., £256.
- SILVER NITRATE**—
Antwerp, 2 cs., £1,210.; Brisbane, 1 cs. (pt.), £16.; Buenos Ayres, 1 cs. (pt.), £12.; Dunedin, 1 cs. (pt.), £19.; Durban, 1 cs., £18.; Colombo, 1 cs. (pt.), £9.; Rangoon, 1 cs. (pt.), £25.
- SOAP**—
Aden, 1 c.; Antwerp, 85 t. 1 c.; Alexandria, 13 c.; Auckland, 15 c.; Amsterdam, 2 t. 19 c.; Antwerp, 20 t. 13 c.; Boulogne, 56 t. 14 c.; Bangkok, 7 c.; Brisbane, 4 c.; Barcelona, 7 c.; Batavia, 17 c.; Bombay, 3 t. 4 c.; Brisbane, 6 c.; Buenos Ayres, 1 t. 1 c.; Cape Town, 1 c.; Calcutta, 1 t. 3 c.; Christchurch, 9 c.; Colombo, 1 t. 6 c.; Constantinople, 19 t. 2 c.; Copenhagen, 10 t. 5 c.; Dantzig, 9 c.; Demerara, 1 c.; Dunedin, 12 c.; Dieppe, 1 c.; Dunkirk, 5 t. 16 c.; Durban, 10 c.; East London, 11 c.; Ghent, 1 c.; Gibraltar, 8 c.; Gothenburg, 1 t. 5 c.; Hong Kong, 17 c.; Helsingfors, 40 t. 9 c.; Haifa, 3 c.; Hong Kong, 2 c.; Hobart, 1 c.; Ipo, 1 c.; Italy, 2 t. 4 c.; Jamaica, 3 c.; Jaffa, 2 c.; Karachi, 18 c.; Kilindini, 2 c.; Madras, 1½ c.; Malmo, 1 t. 10 c.; Mauritius, 16 c.; Melbourne, 1½ c.; Mombasa, 1 c.; Montreal, 6 c.; New York, 12 c.; Ostend, 1 t. 11 c.; Paris, 17 t. 11 c.; Pt. Elizabeth, 3 c.; Rio de Janeiro, 4 c.; Salonica, 1 c.; Shanghai, 1 t. 1 c.; Singapore, 4 c.; Wellington, 5 c.
- SODA**—
Batavia, 5 c., £8.; Pt. Sudan, 7 t., £169.
- SODA ASH**—
Cologne, 185 t., £2,738.
- SODA COMPOUND**—
Alexandria, 15 t., £559.
- SODIUM ARSENITE**—
Cyprus, 8 t., £376.; Durban, 4 t. 1 c., £220.
- SODIUM BENZOATE**—
Cape Town, 3 cs. (pt.), £13.; Mauritius, 1 cs., £14.; Porto Alegre, 1 cs., £17.
- SODIUM BICARBONATE**—
Calcutta, 2 c., £7.; Cape Town, 2 c., £6.; Durban, 6 c., £10.; Fremantle, 1 t. 11 c., £47.; Helsingfors, 3 t. 11 c., £40.; Montreal, 1 t., £45.
- SODIUM BISULPHATE**—
Boulogne, 5 c., £8.; Genoa, 7 drms., £34.; Penang, 2 t. 10 c., £64.
- SODIUM BROMIDE**—
Bombay, 2 cs., £28.
- SODIUM CARBONATE**—
Santiago, Chile, 3 c., £10.; Samarang, 2 cks. (pt.), £6.; Shanghai, 15 c., £8.; Singapore, 3 cks., £13.
- SODIUM CITRATE**—
Melbourne, 1 cs., £7.
- SODIUM HYPO**—
Antwerp, 2 t., £37.; Beyrou, 1 t., £43.
- SODIUM HYPOCHLORIDE**—
Rotterdam, 1 c., £13.
- SODIUM HYPOPHOSPHITE**—
Cape Town, 1 cs. (pt.), £13.; Genoa, 3 cs. (pt.), £50.
- SODIUM HYPOSULPHITE**—
Antwerp, 1 t., £25.; Athens, 8 c., £11.; Bordeaux, 5 t., £90.; Brussels, 1 t., £21.; Samarang, 10 c., £14.; Santiago, Chile, 1 t. 5 c., £33.
- SODIUM IODIDE**—
Naples, 2 cs., £92.
- SODIUM OXALATE**—
Invercargill, 4 cks., £323.; Santos, 1 ck. (pt.), £5.
- SODIUM PHOSPHATE**—
Bombay, 1 t., £29.; Rio de Janeiro, 1 cs., £11.
- SODIUM PRUSSIAN**—
Kobe, 5 t. 13 c., £399.; Philadelphia, 12 t. 1 c., £960.; Yokohama, 10 t. 3 c., £709.
- SODIUM PYROPHOSPHATE**—
Leghorn, 1 t., £70.
- SODIUM SALICYLATE**—
Calcutta, 3 kgs., 1 cs. (pt.), £47.; Colombo, 2 cs., £21.; Durban, 2 cs., £42.; Sydney, 1 cs. (pt.), £6.
- SODIUM SILICATE**—
Cape Town, 8 c., £11.
- SODIUM SULPHATE (GLAUBER SALTS)**—
Lisbon, 5 t. 9 c., £70.
- SODIUM SULPHITE**—
Durban, 12 c., £10.; Kobe, 10 c., £23.; Santiago, Chile, 1 c., £5.; Singapore, 1 t., £24.
- SODIUM STANNATE**—
Dieppe, 1 ck., £64.
- SODIUM SULPHOCARBONATE**—
Calcutta, 1 cs. (pt.), £6.
- SODIUM TARTRATE**—
Melbourne, 1 cs., £8.; Montreal, 2 cks., £70.; Toronto, 5 c., £28.
- STEARINE**—
Wiborg, 15 t.
- STRONTIUM NITRATE**—
Bombay, 20 cs., £99.; Oporto, 2 kgs., £13.
- SULPHUR**—
Amsterdam, 2 c., £8.; Batavia, 2 c., £5.; Dantzig, 2 t. 19 c., £102.; Gothenburg (F.), 5 t., £145.; Gothenburg, 4 c., £20.; Oporto, 2 t. 4 c., £75.; Pernambuco, 3 t. 12 c., £127.; Rio de Janeiro (F.), 10 c., £15.; Yokohama, 1 t., £31.

Piraeus, 10 c., £17.; Rotterdam (F.), 2 t., £53.
- SULPHUR (ROLL)**—
Lisbon, 5 t. 10 c., £146.
- SULPHUR PRECIPITATE**—
Soerabaya, 3 c., £16.; Sydney, 1 c., £4.
- SULPHURIC ACID**—
Calcutta, 1 c., £6.; Colombo, 15 c., £36.; Rangoon, 2 c., £14.; Trinidad, 1 c., £6.
- SULPHUROUS ACID**—
Pt. Elizabeth, 1 ck., £3.
- TALLOW**—
Genoa, 14 t. 19 c.
- TANNIC ACID**—
Antwerp (F.), 1 kg., £13.; Barcelona (F.), 4 cks., £100.; Calcutta, 1 cs., £19.; Calcutta (F.), 1 cs. (pt.), £14.
- TARTARIC ACID**—
Ashburton, 2 c., £39.; Bombay, 8 c., £160.; Calcutta, 1 c., £15.;
- TARTARIC ACID**—
Calcutta (F.), 1 cs., £8.; Durban, 11 c., £200.; Durban, 1 c., £12.; Montreal, 40 c., £620.; New York, 13 t., £1,392.; Rio de Janeiro, 1 c., £25.
- TIN OXIDE**—
Brussels, 4 cks., £155.
- WAX**—
Adelaide, 3 t.; Colombo, £420.
- WHITE LEAD**—
Adelaide, £36.; A'sterdam, £47.; Antwerp, £974.; Auckland, £96.; Beira, £224.; Bombay, £61.; B'deaux, £498.; Boulogne, £489.; Calcutta, £287.; C'church, £55.; Colombo, £14.; Dunedin, £22.; Durban, £49.; E. London, £11.; Lyttleton, £118.; M'bourne, £60.; New York, £3.; Penang, £29.; Pt. Elizabeth, £21.; Rotterdam, £330.; Shanghai, £71.; Timaru, £60.
- ZINC SULPHATE**—
Bombay, 20 cks., £24.
- ZINC SULPHIDE**—
New York, 2 cks., £84.
- MANCHESTER.**
Week ending September 27.
- ACETIC ACID**—
Gothenburg, 8 cs.
- ALUM**—
Quebec, 7 bxs.
- ALUM (CHROME)**—
Bordeaux, 2 cks.
- ALUMINA SULPHATE**—
Bordeaux, 395 bgs.
- AMMONIUM CARBONATE**—
Christiania, 75 pkgs.; Gothenburg, 100 kgs.
- BARIUM CHLORIDE**—
Havre, 1 cs.
- BARIUM SULPHOCYANIDE**—
New York, 4 cs.
- BLEACHING POWDER**—
Gothenburg, 26 cs.
- BORAX**—
Antwerp, 54 bgs.
- COAL PRODUCTS (otherwise undes.)**—
Antwerp, £4,591.; Gothenburg, £1,063.; Havre, £38.
- COAL PRODUCTS**—
Carbolic Acid
New York, 13 pkgs.
- COPPER SULPHATE**—
Ghent, 51 sks.
- DISINFECTANTS (otherwise undes.)**—
Sydney, 697 pkgs.; Treport, 4 cs.
- DYES/STUFFS**—
Tanning Liquid
Antwerp, 60 brls.
- GLYCERINE**—
Bordeaux, 102 cs.
- HYDROSULPHATE**—
Gothenburg, 11 drms.
- MAGNESIUM CARBONATE**—
Bordeaux, 25 kgs.
- SALT**—
Gothenburg, 8,448 pkgs.; Quebec, 3,200 pkgs.
- SALT/CAKE**—
Christiania, 986 t.
- SALTPETRE**—
Bordeaux, 2,500 bgs.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers) ...	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

EDITORIAL NOTICES.

Readers are invited to forward items of intelligence, company reports and balance-sheets, or cuttings from local newspapers of interest to the trades concerned.

Articles, reports, and correspondence on all matters of interest to the chemical and allied industries, home and foreign, are solicited. Correspondents should condense their matter as much as possible, write on one side only of the paper, and in all cases give their names and addresses, not necessarily for publication. Sketches should be sent on separate sheets.

TRANSPORT PROBLEMS.

THE manner in which the essential traffic of the country was maintained during the period of the railway strike—short though it happily was,—leaves behind it a vivid reminder of the difficulties both as regards facilities and charges which face the trading community now, and will continue to do so in the near future. The chemical industries, involved in a process of reconstruction and establishment upon an altogether new and wider basis, will, in the newer branches, feel the effects of the shortcomings of our present transport system far more than the old-established industries, for it is clear that we shall shortly be met with an increase of something like 50 per cent. in the existing freight rates. The bitterness of that knowledge is intended to be sweetened by the consolation that it will be necessary only during the transition period, when the Ministry of Ways and Communications is endeavouring to bring order out of chaos, and to replace an existing wasteful system, hitherto almost solely railways, by something more modern and comprehensive. Unfortunately, as we have seen with wages, these so-called temporary increases have a distasteful habit of becoming permanent, and Ministers, having succeeded in increasing the rates for the carriage of goods over our railway systems, will be in a very strong position, and will have no lack of reasons for maintaining them, if only for the reason that he would be a clever man who definitely could say that the period of transition had come to an end. It is quite clear that the country is sick of subsidies, and therefore we feel that any suggestion of giving preferential treatment to the unstable key industries, to which a measure of fiscal protection has been given already by the Government, would not meet with a very courteous reception. The railway strike has shown the possibilities of road traction, and it

seems now that within economical distances it will probably pay manufacturing firms to undertake themselves the carriage of their goods by road. To some extent, and in the town centres, that has already been done, but we have experience to guide us now, which foretells an early recourse to this mode of transport over much longer distances and with much greater bulk of goods. One of the leading authorities on railway questions has recently said that it would be impossible to establish financial equilibrium merely by increasing rates, and that drastic economies in working expenses are essential. As an abstract theory, of course, that is sound enough, and might have some chance of being tested if the railways had not become what is, in fact, a Government monopoly. Moreover, any chance of testing such a theory seems to be precluded, because—and the fact appears to have been quite forgotten—there have been no published accounts concerning British railways since 1913. Meanwhile, we are given a few figures in Parliament of the millions sterling which are being lost annually over the operation of the British railways, which many people are not at all inclined to accept as gospel. The economies which standardisation of railway rolling-stock and co-ordination of working will bring about are too obvious to need mention, but it seems the settled policy to increase the rates now, and perhaps at some future time to reduce them slightly and then placard the fact that the administration has done certain wonderful things for the traders of the country. As the advantages from the two causes we have mentioned should be large and immediate, it would be well to await the result before adding to the already heavy industrial difficulties by making a large increase on railway rates, after the fashion of the 6s. per ton increase in coal. Meantime, it is the duty of traders themselves to develop other forms of traction, over the management of which they can perhaps have some control.

LABOUR CONDITIONS IN THE CHEMICAL INDUSTRY.

An announcement has been made giving briefly the results of the activities of the Chemical Trade Shift Inquiry Committee, composed of representatives of employers and workmen, and formed for the purpose of inquiring into the position of shiftmen as affected by recent reductions in working hours. On behalf of the workmen it is stated that the conversion from twelve- to eight-hour shifts has been attended by a reduction in earnings of varying amounts, and that no concession was made to shiftmen to correspond with the grant of the 47-hour week to day workers. It was urged, in the first place, that the loss of earnings suffered by the shiftmen should be restored, and, secondly, that the shiftmen should be granted one day off per week, or, alternately, that they should receive a monetary advance. In the case of the day workers, it was asserted that in some cases the introduction of the 47-hour week had resulted in a loss of earnings, and the claim was put forward that that loss should be made good. The workmen's representatives on the committee suggested that minimum

rates of 1s. 6d. and 1s. 8d. per hour for day workers and shiftmen respectively should be fixed. These proposals are to be submitted by the employers' representatives at an early meeting of the Chemical Employers' Federation. The Joint Industrial Council for the Chemical Industry have arrived at an agreement on the question of annual holidays for chemical workers. Subject to continuous and satisfactory service from April 1 of this year, to March 31, 1920, a week's holiday, with full pay, is to be granted to all workpeople.

On this subject attention may be called to the address of Mr. John Allan to the members of the Manchester Section of the Society of Chemical Industry last week. To British chemical manufacturers not the least interesting portion of Mr. Allan's address was his reference to the cost of labour in the German chemical industries. Between a 66-hour week, which was not uncommon before the war, and the eight-hour day, there is a vast difference, but such has been the war-time experience of German chemical manufacturers. In addition, the cost of labour has gone up from 0.65 mark per hour to 1.7 mark, an increase of 90 per cent. The total increase, taking into account the reduced hours of working, is no less than 160 per cent. On the top of this, moreover, there is a very considerable reduction in output per worker, variously estimated at from 25 to 50 per cent., compared with the pre-war output. It will thus be seen that conditions in Germany closely approximate to those prevailing in this country, and British chemical manufacturers have little to fear on this score. On the other hand, and Mr. Allan rightly emphasised the point, the extensions to the German chemical works during the period of the war have been made in no haphazard manner, and the important question of their suitability for peace production has received full consideration.

AUSTRALIAN IMPORTS OF CHEMICALS.

ACCORDING to the report on the trade of Australia in 1918, the imports of chemicals during the year 1917-1918 were valued at £2,480,297., of which £978,260., or 39.4 per cent. originated from the United Kingdom. In the preceding twelve months the total imports were valued at £2,058,415., and in 1913, £1,525,681. The imports of paints and varnishes were valued at £423,397., compared with £666,983. in 1916-1917, the principal decrease being in paints prepared for use, the values for which were £137,264. in 1917-1918, and £362,941. in 1916-1917. This falling-off was due partly to shipping difficulties and partly to the greatly increased local production. The writer of the report (Mr. S. W. B. McGregor) states that the creation of an alkali industry is receiving the attention of the Commonwealth Government, under whose auspices a committee of chemists and users of alkali was formed to investigate the subject. A representative of a leading British firm recently visited Australia, and placed his knowledge at the disposal of the committee. The committee has collected a quantity of useful information, but has not yet made a selection from the number of sites inspected.

SODIUM PEROXIDE.

ITS PROPERTIES AND MICROSCOPICAL CHARACTERS.

By JAMES SCOTT.

SODIUM peroxide has, during comparatively recent years, become very widely adopted in the various branches of textile and kindred industries as a powerful bleacher for fibres of all varieties, of both animal and vegetable origin. It is superior, for many reasons, into the details of which it is not proposed to enter, to the commoner, old-fashioned bleaching agents, and therefore deserves a few remarks. In handling the subject from a microscopical standpoint it may be necessary to repeat a few particulars already known to some readers, but mention of them will make this article comprehensive.

Sodium peroxide, Na_2O_2 , was discovered in 1810 by Thenard and Gay-Lussac. It is prepared on the large scale by igniting metallic sodium in a current of oxygen in aluminium vessels, and is a pale yellow, nominally

Speaking of its practical effectiveness, it must be stated that sodium peroxide is thirteen times stronger in available oxygen than is hydrogen peroxide of ten volumes strength, and eleven times stronger than is the latter of twelve volumes strength. In other words, 11b. of sodium peroxide is equal to 1.3 or 1.1 gallons of ten or twelve volume peroxide respectively. Its bleaching properties depend entirely on the process of oxidation, and the results obtained by its use are consequently reliable and absolutely stable, instead of being of a fugitive character, as is so often the case in connection with chloraceous, sulphurous, and many other bleachers. Typical reactions of sodium peroxide are the following:

No. 1.—One twenty-fourth inch of a layer of sodium peroxide, many of the grains of which have rapidly disintegrated into compound globules; magnified.

No. 2.—One twenty-fourth inch of a layer of sodium peroxide almost instantly reforming under the influence of water; magnified.

No. 3.—One twenty-fourth inch of a layer of sodium peroxide being treated with absolute alcohol. In the complete state sodium hydroxide is formed. Magnified.

amorphous, anhydrous powder, which forms, in conjunction with water, the crystalhydrate, $\text{Na}_2\text{O}_2 \cdot 8\text{H}_2\text{O}$. Its constitution is analogous with that of hydrogen peroxide, so that it is a true superoxide. When dissolved in water it yields hydrogen peroxide and sodium hydroxide.

It is curious to note the old chemists' views on the oxides of sodium. I quote the following sentence from a volume published several years ago: "There are two well-defined compounds of sodium and oxygen—the protoxide, anhydrous soda, NaO ; and the binoxide, NaO_2 , or perhaps tetroxide, NaO_4 ; they are formed by burning sodium in air or oxygen gas." There is no need for comment.

Some chemists prefer to regard the peroxides as having two definite constitutions, the one kind being ordinary peroxides, or simply compounds of an element with a certain proportion of oxygen, and the other—to which group sodium peroxide belongs—being peroxidates, or compounds of an element with hydrogen peroxide, of which latter they are really salts. But this classification does not appear to find much favour, and obviously might lead to general technical confusion.

No other peroxide applicable to bleaching processes is so rich in readily available oxygen as is sodium peroxide. In every 100lb. there are 19.07lb. of available oxygen.

An exceptionally fine, almost vapour-like, dust-cloud rises when bulk quantities of sodium peroxide are disturbed. If sodium peroxide is kept well sealed up from the air, and is meantime stored in a cool position, it remains quite unchanged for very long periods, but owing to its peculiar tendencies it is liable, if carelessly manipulated, to attract moisture and disintegrate. It is hardly safe to allow any of it to stop long in contact with paper, straw, wood, etc., more especially if dampness is prevalent, because its very active oxygen is capable of reacting with water and spontaneously setting such substances aflame. At the same time, one may deliberately make several experiments in this direction without being successful in procuring results of the kind mentioned.

Strictly speaking, sodium peroxide is neither combustible nor inflammable, but if it is brought into contact with incandescent or burning matter it instantly ignites. I held a lighted match to a small piece of the powder and within a few seconds the peroxide fizzled up into a red-hot ball. Naturally, it is to be expected that manufacturers who use sodium peroxide will guard against such possibilities.

Although sodium peroxide is regularly referred to as amorphous, its minute particles possess a semi-crystalline

formation, which is evident upon magnifying the substance.

In my experiments with sodium peroxide I encountered many interesting phenomena. By gently heating a pinch of it upon glass it rapidly changed to a deep yellow colour, and thence to a dark brown one. If the powder is subsequently cooled these colours fade away and the very pale, almost white, tint is restored. A lavender shade temporarily develops during the cooling if the preliminary heating has been strong. When the application of heat is continued long enough the substance fuses, and yields a film crowded with minute globules. This film—a white one—eventually cracks minutely as it cools, and thereby obtains an almost semi-crystalline structure.

Considering that the substance *destroys* colour in other substances it is certainly peculiar that those named are occasioned in these special instances. Like the so-called (and probably *partial*) oxide films on tempered steel—they form rainbow tints,—these spectacles are difficult to explain to the satisfaction of everyone. When a pinch of sodium peroxide is spread on glass its grains quickly dillesce, each separate one, however small it is, becoming liquefied on its own account, with a corresponding increase in the size of the modified object. A remarkable spectacle can be witnessed as multitudes of ordinarily invisible globules of gas escape, and are replaced by others, until equilibrium is obtained. I noticed that the powder which was in direct contact with the glass liquefied first, that which stood away by itself keeping fairly dry for some time.

In No. 1 illustration is shown a typical view of sodium peroxide without added moisture. The mass of minute grains slipped and fell about as they liquefied. The fluid globules eventually solidified into transparent crystalline formations through the evaporation of excess water and demonstration of caustic-carbonate. When a little sodium peroxide is sufficiently moistened with water the crystallohydrates previously alluded to are quickly formed in the fluidised portion of the mass, and appear as minute, flat, transparent crystals of the kind shown magnified in No. 2 illustration. They were accompanied, or preceded, by the development of rosetted clusters (modified globules) and irregular films of broken crystals and bubbles.

Upon *saturating* sodium peroxide with water, hosts of these crystals, along with crowds of ever-changed gas globules, turned and twisted about. This solution, when heated, discharged a mist composed of tiny globules, which settled all round in the vicinity, and subsequently crystallised. The distance to which these ordinarily invisible globules are expelled from the original mass is surprising, but I suppose further reference to this phase of the subject would hardly be relevant.

When sodium peroxide is treated with absolute alcohol at 0° C. (or a solution of hydrogen chloride in alcohol) it forms sodyl hydroxide, a white powder. Some idea of the reaction can be obtained by placing a small quantity of sodium peroxide on glass and dropping some absolute alcohol upon it. The dissolved peroxide is converted into a flaky crystalline substance which appears as shown in No. 3 illustration. The objects, by being tilted up on end among themselves, show rosetted edges. They may redissolve in the surrounding liquid, or unite into a continuous layer or skin. Indeed, they undergo almost inexplicable changes.

If sodium peroxide is placed in a test tube and the alcohol is poured over it, the resultant solution leaves

a sheet of arborescent crystals upon being evaporated. If the excess of deposit is shaken up into the alcohol and some of the milky fluid is poured on to the glass holder, results of like character appear. The alcoholic solution gradually becomes bright yellow, and thence passes into a red one.

NITRATE OF SODA CONSUMPTION IN THE SULPHURIC-ACID CHAMBER PROCESS.

AT the annual meeting of the American Chemical Society, held recently at Philadelphia, Mr. A. M. Fairlie read a paper before the Fertiliser Division on "The Conservation of Nitrate of Soda in the Chamber Process for the Manufacture of Sulphuric Acid."

The author pointed out the lack of uniformity in stating the amount of nitrate of soda consumed in the manufacture of sulphuric acid. The consumption may be calculated on the basis of the sulphur contained in the ore, the sulphur burned out of the ore, or the sulphur in the sulphuric acid produced. In European countries it has been customary to express the nitre consumption in terms of nitric acid of various strengths. The consumption should be expressed in terms of percentage of the nitre consumed on the basis of the sulphur in the acid made. The average consumption of nitre is probably close to 4 per cent. Three and a half per cent. is considered good practice at present, but this is really not a low consumption.

In various acid plants, said the author, the equivalent amount of nitrate in circulation in the chamber system, based on the amount of sulphur in the acid made, will range from about 20 per cent. for brimstone gas to about 50 per cent. for dirty copper blast-furnace gas. Assuming an average of 25 per cent., this means a loss of 3½ lb. out of every 25 lb., or 14 per cent. of the nitre employed in the chamber system.

The nitre, in addition to that in the nitrous vitriol used in the Glover tower, may be added in the following ways: By potting nitrate and sulphuric acid; by introducing nitric acid into the top of the Glover tower; by spraying nitric acid or nitrate in solution into the first chamber, or occasionally in other ways.

Control of the chamber process is effected (a) by observing the differences between chamber temperatures at different points in the system; (b) by observation of the colour of the gases in the chambers or flues; (c) by a combination of both methods.

The best recovery of nitre in the Gay-Lussac tower is obtained when the nitrogen oxides in the gas mixture entering the tower are such that the proportions of nitric oxide and of nitrogen peroxide are such that the combination gives nitrogen trioxide with no excess of either of the constituent gases. In order to secure and maintain this desirable combination of the two oxides of nitrogen, a small quantity of sulphur dioxide is necessary in the gas mixture escaping from the last chamber—just sufficient to keep the required amount of the nitrogen compound reduced to the nitric oxide form. Obviously, continuous analytical control of the gases is indispensable for accurate operation.

The Gay-Lussac tower is not an efficient part of the system from the standpoint of economy in nitre consumption. It is costly, and it involves the handling of enormous quantities of acid both to and from the tower, especially when it is multiplied by two or three, even though a third tower has been found profitable in some plants.

INDUSTRIAL POISONING IN CHEMICAL MANUFACTURE.*

Review of War Years.

By T. M. LEGGE, C.B.E., M.D.†

IN this report for the year 1918, opportunity is taken of reviewing briefly the incidence of poisoning and industrial disease during the last four years—the period of the war. The figures for notification of poisoning by lead, phosphorus, arsenic, and mercury during these years are now published for the first time in the table below. They have great interest, reflecting as they do how important branches of industry were directly or indirectly affected by the dislocation of work, showing an increase of cases in one, and a decrease in another. The figures have the great advantage of being comparative, so that a steady decrease occurring in an industry over a number of years points to a radical change, the

made the processes in which they were employed much safer than they used to be. The number of women attacked was 25 in 1915, 30 in 1916, 45 in 1917, and 20 in 1918, as compared with 68 in 1913, and 70 in 1912. In all cases where special rules or regulations were relaxed to allow of the employment of women, conditions were specified as regards their employment. Thus, in white lead works, only women over 35 years of age were allowed at work in the white beds, none were to be employed for more than eight hours a day, including mealtimes, and food was to be provided before commencing work. Similarly, in paint and colour works, separate and suitable provision was required as to mess-room, cloakroom, washing accommodation, etc. In nearly all instances employers accepted these conditions in the spirit as well as the letter.

From an early date in the war, lead was controlled by the Ministry of Munitions. On its use for Government work, including smelting, conversion into shrapnel, the

*The principal numbers relate to cases, the small figures to deaths. Fatal cases not reported in previous years are included as both cases and deaths.

result either of improved methods of working, or diminution in scope. A stationary position, on the other hand, indicates that ameliorative measures for the time being have reached their limit.

LEAD.

The principal factor to be considered in estimating the position, so far at any rate as lead poisoning is concerned, is whether or not locally applied exhaust ventilation for the removal of dust and fumes is practicable. If it can be applied, great improvement is possible; if it cannot, there will either be an increase in the cases of poisoning, or the numbers will remain stationary. This is borne out by the figures for 1915 to 1918, but they have during this period been considerably affected by other circumstances. The calling up of men led to the increased employment of women in lead industries.

Lead usually takes several months or years to show its effects, and there has been no increase in the number of women reported as suffering. This may be due to the fact that they had not worked long enough, but it may equally be true to say that the greater precautions taken in the removal of lead dust by exhaust ventilation have

manufacture of electric accumulators, sheet lead, and lead piping required for the manufacture of acids, etc., no limits were placed, but wherever private orders were in question the supply was restricted. The heavy pressure placed on firms where smelting of lead was carried on is shown in the figures. Of the total 147 cases, 32 were contracted in the extraction of spelter. The comparatively very high figures for plumbing and soldering were undoubtedly due to the great amount of lead burning required in erecting acid chambers, vats, etc., in large munition factories. The conditions under which the men engaged had to carry on their work, exposed to acid fumes and other defective conditions, were often trying.

Figures referring to white lead, red lead, and paints and colours, may be grouped together. The absence of a single reported case of white lead in 1918 is remarkable, seeing that in 1899 there were 399. The manufacture was rationed to about 50 per cent. of the pre-war output. The works were closed entirely in 1917 for six months, but in 1918 activity in them was considerable—when quantities were manufactured equal to about 60 per cent. of that in pre-war time. Red lead was in great demand, and the figures in 1916 and 1917 show it. In considering the use of lead in the various industries, it has

* Abstracted from the Annual Report for 1918 of the Chief Inspector of Factories and Workshops.

† H. M. Medical Inspector of Factories.

to be borne in mind that not only were we producing material for our own country, but that France and the Allied States relied on us.

Sustained effort will be required to prevent, as far as possible, the cases of lead poisoning from increasing again in peace time. On the practical side little more is to be learnt as to how lead poisoning is caused, and it can be taken as axiomatic that all risk lies in inhalation of dust and fume. These removed or prevented there will be no lead poisoning. At the same time, none of the subsidiary means for minimising effects of lead can be neglected, such as cleanliness of the person, periodic medical examination to detect early signs, so that attention may be directed to points in the process from which dust or fume must be coming off, labour-saving devices, movement study, and industrial research in the effort to find effective substitutes making unnecessary the continued use of the metal.

PHOSPHORUS.

"Phossy jaw" underwent recrudescence in 1915-1918, during which time 11 cases were reported from the one factory in which the manufacture of phosphorus is carried on. Until these cases, an apparent immunity, extending over many years, had been enjoyed. Although the number of individual workers brought into contact with phosphorus for one and another war purpose has been considerable, only one case has been reported in processes other than the manufacture. With this exception, all had worked for years in phosphorus processes. In the factory in question, examination of the dental condition by a surgeon and reference by him to a dentist of those whom he considered needed treatment had been relied on in past years, instead of examination by a dentist in the first instance, which would, in my opinion, have been the wiser course. After the first case (which proved fatal) in 1914, the firm engaged the services of a dentist with the intention, since carried out, of putting the teeth of all those coming into contact with phosphorus into a sound condition, and linking up the work of the dentist with that of a consulting surgeon of the highest standing in case of need. The dentist attends two afternoons a week in the well-equipped dental surgery on the works and quarterly examination of all the workers has been arranged for. This examination has led to the detection of the cases of necrosis, the presence of which was shown after the removal of the decayed teeth. No case has been reported since July, 1918. Dealing with these cases Mr. Thomas (Walsall) reports as follows:

"With three exceptions all the cases reported as suffering from phosphorus poisoning have been employed in connection with the condenser plant. The condenser plant is situated at the back of the furnaces, and the whole is contained in one large lofty building. Men employed in the phosphorus process can be divided into two sections—furnace men and condenser men. It is noteworthy that among the furnace men no cases have been reported. These men do not handle phosphorus, but are subject to the pentoxide fumes of burning phosphorus when any slight leak occurs on the furnace. Although in the same building as the condensers, the fumes from the condenser side do not appear to reach these men to any extent. This is probably due to the heated air rising from the furnace acting as a kind of screen. A much larger number of men are employed in handling phosphorus and phosphorus mud on the condenser side.

"In emptying the condensers the crude phosphorus is syphoned off while in the molten state and run under

water into cast-iron moulds, where it solidifies. After the phosphorus is drawn off, the residues, known as phosphorus mud, are also syphoned off and removed for further treatment.

"During the syphoning and subsequent handling of the crude phosphorus and mud, fumes consisting of the lower oxides of phosphorus arise, and similar fumes come from the mud which has splashed on to the wet floor. It was hardly practicable to remove these fumes by exhaust ventilation as there were so many points of origin. The efforts of the firm were concentrated on improving the condensers and the drainage of floors. Concrete was largely used in place of wood for the condensers, and the floors between condensers were relaid. This improved the conditions, as splashes of phosphorus or mud could easily be swilled away. In addition, the sides of the building were opened up, so as to obtain better general ventilation. With improved condensers improved methods of working were introduced, so as to reduce the amount of handling and consequent exposure to air of the crude phosphorus and phosphorus mud. The amount of fume in the air became noticeably less, but there was still room for improvement. Further experiments were made which have proved that in the future it will be possible to draw off the phosphorus and phosphorus muds from the condensers in such a way that fumes can only escape at one or two points. These points of escape can easily be dealt with by means of exhaust ventilation.

"Two cases of phosphorus poisoning occurred in the amorphous phosphorus department. In this department yellow phosphorus is converted into the amorphous or red variety. The amount of fume in this process is not great, and as the fumes are given off at definite points, they can be dealt with by means of exhaust ventilation. A satisfactory system of exhaust ventilation is now working."

ARSENIC.

The increase of reported cases from three in 1915 to 30 in 1917 was due partly to the increased number of cases (nine), of which an account is given later, from arseniuretted hydrogen gas poisoning, but mainly from the manufacture (for purposes of chemical warfare), of arsenic trichloride by the action of sulphuric acid on a mixture of common salt and arsenic, from whence it distilled over and was condensed as an oily liquid and filled into drums. The plant was difficult to keep free from leaks, and the arsenic chloride permeated the air near the place where the men were working. The effect was to produce an intense irritation, showing itself in eczematous ulceration of the face, nose, hands, and other parts of the body to which the vapour might gain access, especially those parts liable to excessive sweating. The mucous membrane of the eyes, nose, throat, and bronchial tubes was attacked in the same way.

In one case death was due to an accident in the manipulation of the apparatus which led to a burn on the leg extending from the knee to the ankle and half-way round the leg, in a man, aged 46. Professor Delépine, who made the post-mortem examination, and examined the tissues, reported that death was due to absorption of arsenic. It was impossible to determine to what extent arsenic absorption had taken place through the skin, but Professor Delépine expressed the opinion that the amount of arsenic found in all the organs examined indicated that some soluble compound of arsenic had been freely distributed through the body, in all probability by the blood and lymph. Examination

of the hair and urine of other men working on the same plant showed the presence of material quantities of arsenic and indications of degenerative changes in the kidneys. Had the process been continued, further examinations of the urine would have been called for in order to determine the question of the advisability of the men continuing their employment. The symptoms of arsenic trichloride are thus shown to resemble those with which we are familiar from contact with the dusts and salts of arsenic, namely, ulceration of the skin, and quite different from those produced by inhalation of arseniuretted hydrogen gas, cases of which have particular interest owing to their unexpectedness. The pathological changes in the liver and kidneys, however, have a certain similarity which deserves attention.

Two other cases of ulceration of the skin occurred in men who were manipulating sludge containing arsenic from acid coolers in the manufacture of sulphuric acid.

ARSENIURETTED HYDROGEN.

Prior to the year 1914, poisoning by arseniuretted hydrogen gas occurred chiefly in the manufacture of salts of zinc and in chemical works among workmen engaged in removing acid residue from tanks or stills by means of galvanised iron pails and metal shovels. In the years 1900-1913 isolated cases also occurred in such industries as the manufacture of wall papers and the bronzing of art metal. Cases of a similar character have continued to be reported, and during the years 1914-1918 the following industries were concerned: Oil works, cleaning out tanks, two cases, one fatal; chemical works, cleaning out tanks, four cases, two fatal; chemical works, manufacture of zinc salts, two cases, one fatal; chemical works, zinc purification process, two cases, one fatal; brass foundry, bronzing of art metal, two cases.

During the years 1917 and 1918, increase in the manufacture of intermediate dyestuffs has led to a series of other cases, five in number, with two deaths; and the probable extension of this industry adds to their importance. The processes implicated have been those in which zinc dust and hydrochloric acid are used either together in a reduction process or the acid added, at a later stage in the manufacture, as a solvent for the zinc hydrate, formed at the previous stage, and any unconverted metallic zinc. When the first cases were investigated question arose as to the possibility of hydrogen being liberated from an alkaline solution, but subsequent investigation proved this beyond doubt.

The occurrence of these cases of arseniuretted hydrogen poisoning has been due, in some measure, to the high arsenic contents of the acid used during these years. One of the fatal cases occurred on a plant (zinc purification) which had been in operation for 20 years.

The risk of poisoning may in the future be minimised by the use of de-arsenicated acid, but the presence of arsenic in the metal still necessitates the greatest care being exercised in any manufacture where hydrogen gas is liberated in the presence of arsenic. The cases investigated show that even when a process is carried on in the open there is danger to the workmen, or where an exhaust draught is provided for the vessel in which the reaction takes place, this precaution, may, under certain circumstances, be insufficient to protect the workers. Two severe cases occurred in the manufacture of an intermediate dyestuff at a covered vessel provided with such an exhaust, where the anemometer reading, taken at the manhole through which the acid was added, showed an exhaust equivalent to 180-200 linear feet per minute. The explanation of such cases may be that a sudden

evolution of gas, produced in some instances by a too rapid addition of the acid, neutralises the effect of the exhaust and allows the gas to escape into the face of the workman. Complete enclosure of the vessel, in which a slight negative pressure is maintained, with separate feed holes provided with valves, appears to offer the best solution of the difficulty, or where this is impracticable—i.e., where a metal vessel cannot be used,—an exhaust draught must be maintained at the feed holes considerably greater than that referred to above.

The exact interval of time which elapses between exposure to the gas and the onset of symptoms is difficult to determine, owing to the absence of any distinctive physical feature by which the gas can be readily detected. The smell of garlic attributed to the gas has never been observed by any of the persons affected. Generally several hours would appear to intervene before the first symptoms manifest themselves. In one case where frothing of the contents of the vessel occurred, and thus was taken to indicate the escape of gas the man employed became affected after six hours. A point of considerable interest in connection with these cases is the difference in the severity of the symptoms produced by the gas on individuals who are apparently equally exposed. Where two men were doing the same work at the same time, one was very dangerously ill, while the other escaped with no symptoms. The explanation of this phenomenon is difficult.

Periodic examination of the urine of the men engaged on processes involving exposure to the inhalation of arseniuretted hydrogen gas, is unlikely to prove of much value as a preventive measure. Excretion of an excess of arsenic in the urine may be an indication of the ready elimination of the metal from the system preventing a cumulative effect, or on the other hand, as seems more probable, from the results of the examination of the urine of those severely affected, the elimination of arsenic is high where the excretory cells have been damaged, that is, when the symptoms have developed. Safety in working such processes, therefore, depends at present upon the efficiency of the measures taken to prevent the escape of the poisonous gas.

MERCURIAL POISONING.

The figures for mercurial poisoning show an increase in the years 1916 and 1917—caused by the greatly increased use of fulminate of mercury in filling detonators. Only a few of the cases from this cause, however, show the recognised symptoms of mercurial absorption—salivation, tremor, and "nervousness." The great majority were cases of dermatitis or eczematous ulceration of the face, neck, hands, and forearms, associated with conjunctivitis and inflammation of the nasal and laryngeal mucous membrane. The finer the powder the more irritating it is to the eyes and nostrils. The condition is very quickly set up—the reports on the cases frequently showing as short a time of employment as two or three weeks. The cases are but samples, and there must be few who come in contact with the fine powder who do not suffer more or less from its effects. Unfortunately, the highly explosive nature of the substance renders it quite impracticable to require mechanical means of ventilation, and, indeed, operations have to be conducted so carefully that no dust is visible. Use of a 10 per cent. solution of sodium hyposulphite (1lb. to a gallon of water) aids in the prevention of the ulcers and rash, and the workpeople were directed to dip their hands in a basin containing the hyposulphite solution before breakfast, dinner, and leaving at night. Similarly, in

the conjunctivitis, use of a 2 per cent. solution as an eye-wash has been found beneficial. An interesting point brought out by Dr. J. B. G. Skelton, assistant to Dr. O'Donovan at the Ministry of Munitions, who was asked to make an intensive study of the conditions in the factory where most trouble was experienced, is that the supply of a towel to each worker seems to have been more important in reducing incidence than anything else.

(To be concluded.)

ELECTROLYTIC BLEACH.

By A. G. BETTS.

AN American patent has been taken out by the writer in reference to the hypochlorites used in bleaching which are technically limited to the chlorine compounds of caustic lime and caustic soda. The reactions are:

The product then contains equimolecular quantities of hypochlorite and chloride. The second reaction is that taking place when chlorine is absorbed in slacked lime, the universal method of making bleaching powder.

The chloride of lime is dissolved in water as well as possible, and there is a good deal of insoluble matter or sludge, which is somewhat objectionable. The bleach is essentially an oxidising solution, the function of the oxygen being to burn or oxidise the colouring matters and non-celluloses: $\text{CaClOCl} = \text{CaCl}_2 + \text{O}$. This bleach solution is always alkaline owing to the presence of free lime in the bleaching powder, which renders the bleaching slower and less active. The solution can, of course, be exactly neutralised with sulphuric acid, but this is objectionable in some ways, and is not generally done. If the solution is partly neutralised, not much is accomplished, and if overdone the results are not only bad, but unpleasant.

The use of a lime bleach has certain objections, such as the precipitation of insoluble lime compounds in the fibres, making them harsh, so when the cost permits the lime bleach is first converted to soda bleach with soda ash, carefully using some sodium bicarbonate to correct alkalinity.

To explain electrolytic bleach and its manufacture, if a solution of common salt, sodium chloride, is electrolysed with an insoluble anode, that is graphite or platinum, and graphite, platinum or iron, cathode, using 4 or 5 volts per cell, primarily the salt is decomposed by the electric current thus: $\text{NaCl} = \text{Na} + \text{Cl}$. The sodium is liberated at the cathode, but not as metallic sodium, on account of the presence of water with which sodium reacts thus: $\text{Na} + \text{H}_2\text{O} = \text{NaOH} + \text{H}$, evolving hydrogen gas, which bubbles away, and a solution of caustic soda results at the cathode. As chlorine is somewhat soluble in water, a solution of chlorine simultaneously appears at the anode. The two solutions mix almost immediately because of the motion of the solution, which is actively maintained by the streams of hydrogen bubbles and reacts thus: $2\text{NaOH} + 2\text{Cl} = \text{NaOCl} + \text{NaCl} + \text{H}_2\text{O}$. As this mixing must go on continuously, no diaphragms are permissible as in electric caustic-soda plants, making the plant much simpler and cheaper.

The product is a solution of sodium hypochlorite and unchanged salt, and if a neutral solution is used the product is neutral. As the treatment of the solution is continued for conversion of salt to hypochlorite, un-

fortunately the hypochlorite itself reacts to a greater and greater extent as its strength increases, both at the cathode and to a less extent at the anode, so that to realise a reasonable efficiency of the electric current and get output from the cells the process has to be cut off, while much salt remains undecomposed, or practically the salt solution has to be fed to the cells at a sufficiently rapid rate so that the overflow contains quite a little less hypochlorite than would be desired, except in cases where salt is very cheap, when the salt consumption would not make so much difference.

Principally the loss of the hypochlorite arises because it is again reduced by the electric current back to salt, and there is also a comparatively smaller loss of hypochlorite by oxidation to the useless chlorate at the anode. The hydrogen bubbles coming off at the cathode have no reducing effect, but the reduction takes place at the cathode surface. There have been certain ways of preventing this cathode reduction, but they have no value for electrolytic bleach. One method is to use platinum cathodes and add to the solutions sodium chromate or bichromate, which acts very perfectly in preventing reduction, but the platinum, of course, is very expensive, and the chromates impart a very persistent yellow colour. The other method, of adding calcium chloride to the solutions, which plasters the cathodes with a deposit of calcium hydrate, is very imperfect, and causes more loss by increasing the voltage, and hence power consumption, more than it is worth, and also causes a good deal of hypochlorite to go over into chlorate.

The writer made the discovery that if a magnesium cathode is used there is practically no cathode reduction, owing to the formation automatically of a film of magnesia hydrate on its surface, which prevents the hypochlorite from reaching the actual cathode surface. By the use of this cathode it is possible to increase the current efficiency, percentage of salt converted to hypochlorite, and strength of the solution in available chlorine. The electrolytic bleach made with magnesium cathodes is necessarily and automatically completely neutral, and it has been found that neutral electrolytic bleach is materially more active and efficient than bleaches prepared by chemical methods.

In general, in making electrolytic bleach the salt used should be free from calcium and magnesium salts, and if present they should be removed by soda treatment, and heavy metals—iron, lead, copper, etc.—should be avoided in construction, which should rather be of concrete with wood solution pipes, or, better, of tile or stoneware.

The preparation of electrolytic bleach is an extremely simple process, requiring merely to cause a solution of salt water to flow to the cells, which are themselves simple, and the overflow passes to the bleach storage tank.

The plant is much simpler and cheaper than electrolytic caustic soda and lime bleach plant, and has much to recommend it, except in cases where salt and power are expensive. The actual cost of production of bleach by electrolysis will, of course, vary from place to place, according to the scale on which operations are conducted, cost of power, cost of salt, etc. One important thing about it is that it can be used advantageously on a small scale as well as on a large one, because no skilled labour and supervision are required to operate the process.

The loss of magnesium is very small. Magnesium is somewhat attacked by salt water, although the action is very slow; but while the electric current is passing, the magnesium is actually covered with a thin film of the electrolytically produced caustic which protects it.—*Dyer and Calico Printer.*

THE GERMAN CHEMICAL WORKS.

MR. JOHN ALLAN, the newly elected chairman of the Manchester Section of the Society of Chemical Industry, delivered an extremely interesting opening address at the first meeting of the Section, held at the Grand Hotel, Manchester, on Friday of last week, the title being "Notes on the Rhineland Chemical Works." As a member of the mission which, on behalf of the Association of British Chemical Manufacturers, recently inspected the large chemical works in the occupied area of Germany, Mr. Allan was singularly well qualified to deal with this subject.

The speaker, in the introductory portion of his address, stated that much had been said of the greatness of the chemical works and the marvellous efficiency of their management, but whilst he had no desire to under-rate the developments in applied chemistry that had originated in Germany, he asserted that the German manufacturers had no monopoly in the ability to initiate such enterprises and bring them to fruition. Not the least important of the many causes which had contributed to the position of the German chemical industry was the possession of the Rhine valley, along which were situated many of the greatest of Germany's chemical works. The river provided a means of transport for raw materials and finished products, water supply for manufacturing operations, and a means of disposing of trade effluents. In close proximity was to be found, in the readily available deposits of brown coal, a supply of fuel at little more than nominal cost.

BANKING FACILITIES.

After briefly sketching the outstanding events in the history of the German chemical industry, Mr. Allan referred at some length to the facilities offered by German banks to manufacturers. German industrial enterprise, he said, owed a great part of its success to the close association with the national banking interest. The directors of the banks saw to it that any appeal for public money which they associated themselves with should be satisfactorily reported upon by their staff of industrial experts, and that their arrangements as to capital, management, and scientific assistance were approved. Such co-operation was one of the principal factors in the success of German industries. In the case of an enterprise abroad, financed by a German bank, it was stipulated in the agreement that all orders for materials should be placed with German firms—generally firms in which the bank had a financial holding.

The speaker then dealt, in turn, with such questions as the training and remuneration of research chemists and chemical engineers, and the standardisation of chemical plant. It was noteworthy, he said, that invariably the chemist held the right of final decision as to the arrangement and construction of chemical plant in the German works. The chemical engineer was responsible for the engineering work only; for example, the strength of materials used, the efficiency of power application, and so on. The erection of chemical plant, said Mr. Allan, was undoubtedly greatly facilitated by the standardisation of many parts, and it was to be hoped that with the increasing demand for such materials in this country, the knowledge and technique which provided the German chemical manufacturer with a wide range of excellent plant materials would be rapidly acquired here.

LABOUR AND WAGES.

On the question of hours of labour and rates of wages as affecting the German chemical industry—a subject of much interest to British manufacturers,—Mr. Allan emphasised the point that present conditions were in all probability transitory in character, and that it was impossible to forecast the future state of labour either in Germany or in other countries. Before the war long hours were general throughout Germany, and wages in the chemical industry were variable. As an example of the changes that the war had brought about, the experience of one of the largest works engaged in the manufacture of chemicals was cited. Before the war a working week of 66 hours was the rule, and the wages paid to general labour averaged 0.65 mark per hour, or a total of 43 marks per week. With the adoption of the eight-hour day, the same labour now cost 1.7 mark per hour, or 81.6 marks per week, an increase of 90 per cent. in wages and a reduction of 28 per cent. in the hours of working. Assuming that the output per workman had remained unchanged, the cost of labour, allowing for the reduction in working hours, had risen to 112 marks, or an increase of 160 per cent. compared with the pre-war wage.

Moreover, it was quite commonly asserted, said Mr. Allan, that the character of labour had considerably altered, both in discipline and in the quality of work done, the general assertion being that the possible output was now only 50 per cent. of what it was before the war. That statement probably included the reduction following upon the lessened number of hours worked, as well as that arising from lowered efficiency, as figures derived from certain branches of industry showed a minimum reduction in output of about 25 per cent. With fuller employment it might be assumed that present conditions would be modified, but one could not help feeling that the old conditions would not return.

WORKS EXTENSIONS.

Some notice should be taken of the present conditions of the German chemical factories and the changes which had been made in them during the period of the war. Those factories with facilities for manufacturing explosives or gas warfare materials had greatly extended their plant, full consideration having been given to the possibility of utilising the extensions for industrial purposes after the war. Generally, it was left to the factory control to provide for increased outputs by such means as they chose to adopt. Every facility was afforded by the German Government as regards materials, labour, and finance.

Apparently the system of financing the extensions to factories, said Mr. Allan, had been that of repaying from time to time the expenditure incurred. In a number of cases, however, in which large plants had been erected on behalf of the Government during the later period of the war, repayment had not taken place, and firms were the possessors of very expensive plant and buildings which in normal circumstances they would not have erected. It was feared that the abnormal cost incurred by these extensions would not be met by the new Government, and that the firms themselves would have to bear the greater part, if not the whole, of the expense. Those circumstances, it was pointed out, applied only to work carried out during a late period of the war. Many enlargements of plant had been effected on such terms that capital charges upon the peace output would not be excessive.

In general, the plant of the German dye-manufacturing concerns was in excellent condition, and in many cases the producing capacity had been considerably increased as a result of the war. If competition with German dyes and pharmaceutical products was difficult before the war, it would be no less so in the future, when efficient plants and large-scale production would be important factors in the cost of production.

SYNTHETIC NITRATES.

Turning to the developments that have taken place during the war in the fixation of nitrogen, Mr. Allan referred to the plants at Oppau and Merseburg for the direct synthesis of ammonia from atmospheric nitrogen and hydrogen, and to the Höchst and Leverkusen plants for the oxidation of ammonia to nitric acid. These plants were monuments to the skill of the chemists and engineers who had erected them. The Höchst plant housed 256 platinum catalyst vessels, with a total monthly capacity of 8,000 tons of 100 per cent. nitric acid. The plant was erected in six months at a cost of £2,000,000., and was put into operation in February of last year. A feature of this and many other plants for various purposes was that though the aggregate output was very great, the plant itself was made up of a number of units, each self-contained. Increased output was attained by the erection of a fresh series of units. The advantages of this system were numerous.

A very noticeable feature of the large German chemical works was that the manufacture of an article was not undertaken unless in some way it was connected with the essential part of the firm's business. As an example, the speaker cited the manufacture of superphosphate of lime at the Bayer Company's Leverkusen works for the purpose of utilising waste acid, the superphosphate plant having a capacity of 50,000 tons per annum.

Apart from the very large German chemical firms there were numerous smaller ones, many of which, particularly those manufacturing heavy chemicals, were as badly equipped as the most antiquated of our English factories. On the other hand, some of the smaller works were as efficiently controlled as the large ones. The products of most of these were usually of a specialised character. The small works were often useful to the large ones, as they manufactured necessary products, the consumption of which was too small to justify the large manufacturers taking up their production.

A vote of thanks to the author, moved by Mr. E. Ardern and seconded by Mr. F. H. Terleski, was carried with acclamation.

STUDY OF *N*-BUTYL SUBSTITUTION IN THE ARYLAMINES.*

By J. REILLY, D.Sc., AND W. J. HICKINBOTTOM.

THE *n*-butyl substituted arylamines have been investigated hitherto to a very limited extent, probably because *n*-butyl alcohol has been available only in small quantities. Now that it is possible to obtain this alcohol in large amounts, its utilisation, industrially, in the preparation of dyestuffs and other technical organic compounds, is a matter for consideration. It also has been observed that the *p*-nitroso derivatives of the higher alkylanilines have marked physiological properties.

The simplest *n*-butylarylamine is *n*-butylaniline, which has previously been obtained as a by-product only in

the condensation of *n*-butyraldehyde with aniline (Kahn, *Ber.*, 1885, 18, 3361). The preparation of *p*-nitrosodibutylaniline and *p*-phenylene di-butylamine was unsuccessfully attempted by Karrer (*Ber.*, 1915, 48, 1393). He claimed that the di-butyl and diamylanilines acted differently from the lower alkylanilines.

It is, therefore, of interest to carry out a more detailed examination of these *n*-butyl derivatives. When *n*-butyl chloride and aniline were heated under reflux a mixture of mono- and di-butyl anilines was obtained. From the mono-*n*-butylaniline the *p*-nitroso derivative was obtained, which yielded, on reduction, the corresponding phenylenediamine. *as*-Phenyl-*n*-butylhydrazine was also prepared, and from it diphenyl-di-*n*-butyltetrazone. The latter compound is characterised by a series of colour changes on standing in presence of aqueous alcohol. Di-*n*-butylaniline gave a liquid *p*-nitroso compound which yielded a number of addition compounds with metallic salts. Reduction of *p*-nitroso-di-*n*-butylaniline gave *p*-phenylene-di-*n*-butyldiamine, identical with the diamine obtained by reducing the azo compound formed by coupling diazotised sulphanilic acid with di-*n*-butylaniline in acetic-acid solution. This result is at variance with those of Karrer.

The *n*-butyl-*o*- and *p*-toluidines were prepared similarly to the *n*-butylanilines, but in this case it was observed that di-*n*-butyl-*o*-toluidine could not be obtained by the action of *n*-butyl chloride on mono-*n*-butyl-*o*-toluidine, while *p*-toluidine yielded both mono- and di-butyl substitution products. Mono-*n*-butyltoluidine on nitration in presence of an excess of concentrated sulphuric acid yielded 2-nitro-*n*-butyl-*p*-toluidine, which on further vigorous nitration gave 2:3:5-trinitro-*n*-butyl-*p*-tolynitramine. Nitration of *n*-butyl-*p*-toluidine yielded successively 3-nitro-*p*-toluidine, 3:5-dinitro-*n*-butyl-*p*-toluidine, and the nitroso and the nitramino derivatives of the above compound. With the latter two compounds, various experiments were carried out on the elimination of the nitroso and nitramino groups. It was shown that boiling alcohols and sunlight are able to remove these two groups.

A study was made of the formation of the *n*-butylarylamines by condensation of the alcohol with the amine in the presence of hydrochloric acid or a similar condensing agent. It was found that by carrying out the reaction at 200°, appreciable amounts of a primary amine were obtained, and its presence was ascertained to be due to the intramolecular change of the *n*-butylaniline. This compound has been proved to be 4-amino-*n*-butylbenzene. A study of the literature revealed the fact that it is probable that *iso*-butylaniline yields 4-amino-*tert*-butylbenzene on heating with hydrochloric acid in a sealed tube, so that there is a difference in the behaviour of the two butylanilines. *Sec*-butylaniline undergoes intramolecular rearrangement in a normal manner, yielding 4-amino-*sec*-butylbenzene.

In certain of the substances containing a *n*-butyl group attached to the aminic nitrogen, the colour of the compound differs from that of the corresponding methyl or ethyl derivative produced. Certain dyestuffs which have been prepared containing *n*-butyl groups also give different colours compared with the colour of the corresponding lower alkyl derivative. A detailed comparative study (absorption spectra, shade of dye on various materials, etc.) of dye-products of the *n*-butyl series would be of interest.

*Paper read before the Chemistry Section of the British Association at Bournemouth.

BRITISH OVERSEAS CHEMICAL TRADE IN 1918.

WE give below extracts from the annual statement, just issued, of the trade of the United Kingdom with foreign countries and British Possessions in 1918, compiled by the Customs and Excise Department. The figures relating to the chemical and allied trades will be found much more useful than those given in the monthly Board of Trade returns, owing to the detailed analysis of the countries of origin of imported, and the destinations of exported, chemical products. Each product is specified separately, together with the extent of the trade done with the more important countries, the corresponding figures for 1917 being in parentheses.

IMPORTS.

Acetate of Lime.—United States, — (8,606cwt.); other foreign countries, 560cwt. (3,932cwt.); Canada, 21,199cwt. (30,643cwt.); total, 21,759cwt. (43,181cwt.).

Acetic Acid.—Germany, 11cwt. (—); Netherlands, — (600cwt.); Switzerland, 573cwt. (1,676cwt.); United States, 11,357cwt. (101,979cwt.); Canada, 77,812cwt. (92cwt.); total, 89,753cwt. (104,347cwt.).

Acetone.—United States, 138,291cwt. (100,415cwt.); Canada, 35,691cwt. (25,029cwt.); total, 173,982cwt. (125,444cwt.).

Bleaching Powder.—Germany, 28cwt. (—); United States, — (3,247cwt.); total, 28cwt. (3,247cwt.).

Other Bleaching Materials.—Total from foreign countries, 40cwt. (—).

Boracite.—Foreign countries, 6,546cwt. (—).

Borate of Lime.—United States, 19,852cwt. (55,742cwt.); Peru, 8,780cwt. (11,300cwt.); Chili, 121,974cwt. (165,911cwt.); Argentine Republic, 11,918cwt. (—); total, 162,524cwt. (232,953cwt.).

Borax.—France, 2,757cwt. (16,526cwt.); United States, 13,728cwt. (20,963cwt.); total, 16,485cwt. (37,489cwt.).

Sulphur.—Italy, 1,202,910cwt. (342,979cwt.); United States, 251,455cwt. (242,560cwt.); other foreign countries, 28cwt. (2,296cwt.); total, 1,454,393cwt. (587,835cwt.).

Carbide of Calcium.—Sweden, — (24,123cwt.); Norway, 404,347cwt. (294,040cwt.); Canada, 112,915cwt. (58,245cwt.); total, 517,262cwt. (376,408cwt.).

Coal Products, not Dyes.—France, — (114cwt.); United States, 8,194cwt. (37,144cwt.); other foreign countries, — (110cwt.); British Possessions, 5,467cwt. (5,394cwt.); total, 13,661cwt. (42,762cwt.).

Cream of Tartar.—France, 20,320cwt. (21,848cwt.); Portugal, 2,239cwt. (1,499cwt.); Spain, 9,589cwt. (4,694cwt.); Italy, 7,045cwt. (10,014cwt.); United States, 451cwt. (285cwt.); other foreign countries, 57cwt. (48cwt.); total, 39,701cwt. (38,388cwt.).

Glycerine, Crude.—Netherlands, 9,920cwt. (—); France, 19,681cwt. (2,767cwt.); Spain, 7,297cwt. (586cwt.); United States, 23,994cwt. (1,762cwt.); Argentine Republic, 2,100cwt. (2,785cwt.); other foreign countries, 189cwt. (—); British Possessions, 309cwt. (—); total, 63,490cwt. (7,900cwt.).

Glycerine, Distilled.—Netherlands, 7,076cwt. (13,041cwt.); United States, 21,968cwt. (2,789cwt.); other foreign countries, 642cwt. (1cwt.); British Possessions, 99cwt. (—); total, 29,785cwt. (15,831cwt.).

Nitrate of Potash.—Foreign countries, — (910cwt.); British India, 383,689cwt. (396,508cwt.); total, 383,689cwt. (397,418cwt.).

Muriate of Ammonia.—Foreign countries, — (215cwt.).

Potash Compounds, Other Sorts.—Russia, £98,310. (£40,728.); Sweden, £350. (—); Germany, £1,463. (—); Netherlands, £2,770. (—); France, £52,118. (£31,553.); Japan, £84,967. (£66,335.); United States, £37,920. (£139,228.); other foreign countries, £23,418. (£26,177.); Anglo-Egyptian Soudan, £34,986. (—); British India, £104,732. (£6,416.); other British Possessions, £9,023. (£18,718.); total, £450,057. (£329,155.).

Soda Ash.—Total from foreign countries, — (2,580cwt.).

Soda, Caustic.—United States, 109cwt. (15,571cwt.); other foreign countries, 270cwt. (247cwt.); British Possessions, — (120cwt.); total, 379cwt. (15,938cwt.).

Soda, Crystals.—British Possessions, 220cwt. (—).

Soda Compounds, Other Sorts.—Sweden, 2,123cwt. valued at £10,351. (2cwt., £8.); Norway, 43,831cwt., £123,774. (55,551cwt., £107,231.); Germany, 255cwt., £135. (6cwt., £22.); Netherlands, 396cwt., £2,912. (1,023cwt., £5,610.); France, 11,320cwt., £53,356. (7,464cwt., £36,425.); United States, 33,393cwt., £213,895. (36,945cwt., £170,962.); other foreign countries, 927cwt., £4,091. (936cwt., £19,989.); British Possessions, 753cwt., £3,493. (2,126cwt., £6,664.); total, 92,998cwt., £412,007. (104,053cwt., £346,911.).

Sulphuric Acid.—United States, 1,886cwt. (4,807cwt.); other foreign countries, — (240cwt.); total, 1,886cwt. (5,047cwt.).

Tartaric Acid.—France, 1,632cwt. (1,377cwt.); Italy, 13,348cwt. (14,205cwt.); British Possessions, — (150cwt.); total, 14,980cwt. (15,732cwt.).

Chemicals, Unenumerated.—Russia, £10,000. (£1,075.); Sweden, £9,917. (£166,530.); Norway, £602,819. (£568,394.); Denmark, £69,173. (£46,412.); Germany, £1,349. (£1,363.); Netherlands, £92,625. (£95,014.); France, £170,636. (£130,038.); Switzerland, £40,523. (£61,373.); Portugal, £32,114. (£9,117.); Spain, £219,413. (£7,643.); Italy, £294,980. (£303,739.); China, £2,256. (£1,135.); Japan, £151,108. (£77,887.); United States, £864,837. (£794,274.); Chili, £15,268,702. (£6,365,716.); other foreign countries, £31,072. (£180.); Hong Kong, £17. (—); Australia, £38,415. (£29,619.); Canada, £114,311. (£109,795.); other British Possessions, £15,977. (£14,809.); total, £18,030,444. (£8,784,113.).

Chemical Manufactures, Total Value of.—From foreign countries, £23,483,006. (£12,870,854.); from British Possessions, £2,140,725. (£1,307,285.); total, £25,623,731. (£14,178,139.).

Bones for Manure.—Netherlands, — (371 tons); France, — (1,133 tons); Brazil, 5 tons (15 tons); Uruguay, — (4 tons); Argentine Republic, 2,564 tons (421 tons); other foreign countries, 40 tons (68 tons); Egypt, 2,345 tons (1,219 tons); British India, — (457 tons); other British Possessions, 190 tons (182 tons); total, 5,144 tons (3,870 tons).

Nitrate of Soda.—Chili, 300 tons (1,190 tons).

Phosphate of Lime and Rock Phosphate.—Netherlands, 666 tons (734 tons); Dutch West Indies, — (1,930 tons); Algeria, 32,871 tons (70,812 tons); Tunis, 413,633 tons (144,443 tons); United States, 13,361 tons (44,982 tons); other foreign countries, — (4,304 tons); Egypt, 400 tons (9,412 tons); other British Possessions, 3,941 tons (—); total, 464,872 tons (276,617 tons).

(To be continued.)

AUSTRALIAN METALS AND MINERALS.

PRIOR to the declaration of war by the United Kingdom, practically the whole of the base metal production in Australia had been sold to representatives of the German metal organisation. The outbreak of hostilities threw the industry into chaos, and steps were immediately taken to cancel existing agreements, and to establish the industry on a sound and permanent foundation, consistent with British interests.

The following legislative and administrative acts are cited by Mr. S. W. B. McGregor, H.M. Senior Trade Commissioner in Australia, in his report on the trade of Australia in 1918:

(1) Cancellation of all mineral and metal contracts with enemy companies and firms.

(2) Dissolution of the Lead Convention controlled by Germans, which determined the price to consumer and producer of all Australian lead.

(3) Dissolution of the Zinc Combine, a purely German combine which controlled the world's spelter market, determining price, output, and manipulating the market as it pleased in the interests of Germany.

(4) Elimination of the German interests in the copper industry in Australia.

(5) Elimination of all enemy agencies controlling tin, molybdenite, wolfram, and other metals.

The policy of the Government is to have all metallic ores, as far as possible, treated within the Commonwealth, so that the resultant metals can be marketed in a refined state.

Steps taken by the Commonwealth Government resulted in the formation and extension of the Broken Hill Associated Smelters' Proprietary, Limited, which has taken over the Broken Hill Proprietary Works at Port Pirie, South Australia. The new company is a co-operative institution for the smelting of silver-lead ores and concentrates and the refining of the silver-lead bullion. It has one of the largest silver-lead smelting works in the world, with a capacity for an output of 160,000 tons of pig lead and 5,000,000 to 6,000,000 ounces of silver per annum. The Sulphide Corporation, Limited, has improved and enlarged its lead-smelting works at Cockle Creek, near Newcastle, New South Wales. The refinery plant is now in operation, and the output of some 30,000 tons of lead per annum, with silver and gold, made available locally. The Fremantle Smelters, Fremantle, Western Australia, are owned by the Fremantle Trading Company, Limited. The plant, running at its full capacity, is capable of an annual output of 8,000 tons of pig lead or silver-lead bullion from usual grade lead concentrates. The company is at present smelting only the Northampton lead ores, which contain little or no silver, and the present output is at the rate of 5,000 tons pig lead per annum.

A new company, the Zinc Producers' Association Proprietary, Limited, has been formed to control and dispose of the output of zinc concentrates produced within the Commonwealth. All the principal zinc-producing companies are members, and the association is founded on a co-operative basis. The Commonwealth Government are represented on the board, thus safeguarding the interests of the general community. Under an agreement with the Zinc Producers' Association, the Imperial Government are to take 250,000 tons of zinc concentrates per annum for the period of the war and one year thereafter, and 300,000 tons per annum for the succeeding nine years. The Imperial Government also have an

option on the balance of production, subject to certain reservations. The output of zinc concentrates within the Commonwealth for the 12 months ended December 31, 1917, was 284,662 tons, and arrangements have been made whereby 40 per cent. of the normal output may be reserved for local treatment. The 1918 output was 345,017 tons.

A new company, the Copper Producers' Association Proprietary, Limited, has been formed on the same lines as the Zinc Producers' Association, to control and dispose of the output of copper produced within the Commonwealth. All the principal copper-producing companies are members of the Association. As in the case of the Zinc Producers' Association, the Commonwealth Government are represented on the Board of Directors. The Australian production of copper amounts to approximately 40,000 tons per annum. The whole of this copper is refined in Australia.

Encouragement is also given to the refining of tin ore and tin concentrates within the Commonwealth. The principal tin smelters are the Mount Bischoff Company, Tasmania, the Sydney Smelting Company (Pyrmont Works), New South Wales, and the Irvinebank Company, Queensland.

The Commonwealth Government entered into an agreement with the Imperial Government for the acquisition of all wolfram, molybdenite, etc., produced in Australia. Under this agreement practically the whole of these minerals produced in Australia have, during the war, been acquired for the Imperial Government, the prices fixed from January 1, 1918, being: Wolfram and scheelite, 65 per cent. WO_3 , 52s. 6d. per unit at producing centres; molybdenite, 85 per cent. MoS_2 , 100s. per unit at producing centres.

Another action of the Government towards the elimination of German influence was the creation of an Australian Metal Exchange, with offices at Melbourne and Sydney. No metals or minerals can be exported from Australia unless first registered with the Exchange by an active member, and, during the war, with the consent of the Minister of Trade and Customs. The members of the Exchange must be natural-born British subjects, and the Attorney-General has the right of veto with regard to membership during the war and 12 months after.

THE STUDY OF CATALYSIS.

MR. HUGH S. TAYLOR, in the course of an article in *Nature* (October 2), states that the modern curriculum of theoretical chemistry should concern itself largely with the scientific principles involved in catalytic reactions. An extended experience with catalysis, both pure and applied, has demonstrated that, from a complete realisation of the theoretical aspects of the problem, progress in the application follows the more rapidly and the more certainly. It is astonishing to note the facility with which new progress is attained by the employment of the scientific principles which have been acquired in a totally different application of catalysis to industrial progress. The records of certain of the Government Departments of investigative work, during the last few years, would be instructive in this regard. The need, therefore, is urgent for a well-trained force of young students, versed in the fundamentals of this modern branch of chemistry, and equipped to take their place in the further developments which lie so close at hand. There are manifold possibilities ahead—numerous processes and agencies catalytic awaiting the facile brain and hand of the investigator.

ITEMS OF INTEREST.

OBITUARY.—We regret to announce the death of Mr. W. G. Smith, who was associated with the firm of R. W. Greeff and Co., London, for the past thirty-five years. Mr. Smith had a very large circle of friends and was widely known throughout the chemical and colour trades. The funeral took place at West Norwood Crematorium on Thursday of last week.

ZINC AND ZINC DUST PRICES.—There is no change to report in the price of Australian high-grade zinc dust (88-92% metallic zinc), which remains at £68. to £70. per ton, c.i.f. United Kingdom. The price of Australian electrolytic zinc, containing 99.95% metallic zinc, is unchanged at £42. per ton, f.o.b. Australia, for direct shipment to New Zealand, India, South Africa, and the Far East.

CHEMICAL WORKS ANNIVERSARY.—October 4 was the anniversary of a chemical combine on Tyneside which has had far-reaching results. On October 4, 1794, John Losh, in partnership with the Earl of Dundonald as chemical manufacturers, took out a patent for the manufacture of sulphate of soda and caustic soda at the Bell Close Works, Scotswood-on-Tyne. Three years later the company was formed into the Walker Alkali Company, which became one of the most successful works in the country.

CHEMICAL ENGINEERING LECTURES AT MANCHESTER.—An important course of twenty lectures on various aspects of chemical engineering has been arranged by the Department of Applied Chemistry at the College of Technology, Manchester. The lectures will be given weekly, the first having been arranged for Tuesday next, October 14, at 4.30 p.m., when the lecturer will be Mr. E. L. Rhead, on "Inherent Faults in Metallic Materials Used in the Construction of Chemical Plant." The fee for the course is £2. 2s., and for single lectures 5s.

NEW ANALYTICAL METHOD.—In the novel method of chemical analysis developed in the research laboratory of the General Electric Company (U.S.A.), a beam of X-rays, passed through a filter to remove all except a single wave-length and through two slits to narrow it to about one twenty-fifth of an inch, traverses a small tube of the pulverised material under examination, and is received by a photographic film. The exposure may be from one to twenty hours. The developed film shows the over-exposed centre, with lines on each side caused by reflections from tiny crystals, and every line indicates a set of planes of some important atom. Interpretation of the line patterns of different crystalline structures has already identified some compounds and even component elements in some mixtures.

NEW PHOTOGRAPHIC DEVELOPING AGENT.—Mr. Herbert A. Lubs, of the colour laboratory of the United States Bureau of Chemistry, has investigated the preparation of *p*-aminocarvacrol and its use as a developing agent in photography. It is conveniently prepared from carvacrol by the production of nitroscarcavrol, and the reduction of this by ammonium sulphide. Five grammes of the pure derivative were obtained from 10 grammes of carvacrol. As a developer for prints *p*-aminocarvacrol was found to be as good as metol, *p*-aminophenol, or *p*-aminocresol, and the lasting quality of the mixed developer was superior to that of *p*-aminophenol, but not quite so good as that of the others. This work has been done particularly with the view of utilising the abundant source of carvacrol that may be prepared from cymene. Thymoquinol and *p*-aminothymol were also prepared, but they proved to be less satisfactory both with regard to yield and their behaviour as developing agents.

ANALYSIS OF FERROSILICON.—A complete analysis of ferrosilicon involves the determination of many elements in addition to iron and silicon—viz., carbon, manganese, phosphorus, sulphur, calcium, magnesium, barium, and aluminium, and direct determinations are difficult and laborious, some elements comprising silicon itself being sometimes estimated by the difference in method. In bringing the subject before the American Electrochemical Society, Mr. Earl M. Anger, of New York, insisted upon the necessity for very careful sampling of the ferrosilicon. In high-grade alloys the segregation of the silicon from the iron silicide is very pronounced, the silicon going to the top when the cast is cooling. For the determination of the silicon itself, Anger opens the alloy up with sodium carbonate; in alloys of more than 25 per cent. of silicon, this melt would attack the platinum crucible, and the carbonate is replaced by sodium peroxide, rather than by sodium hydroxide, in iron (not in nickel) crucibles. These recommendations were questioned by H. R. Power, of the Carborundum Company, who prefers nickel and the peroxide.

CERAMIC SOCIETY.—In view of the railway strike, the Emergency Committee of the Ceramic Society decided to postpone the autumn meeting of the Refractory Materials Section, which was to have been held at Stoke-on-Trent on Wednesday and Thursday of this week, until the end of April, 1920. This will cancel the spring meeting arranged to be held in London next year. The autumn meeting in 1920 will be held in the United States.

NEW SCOTTISH DYE-MAKING FACTORIES.—Progress is being made with the erection of the factories near Grangemouth for the Scottish Dyes, Ltd. The site covers 80 acres, and has sea, railway, and canal facilities. The directors of this company hope to secure a leading place in the production of dye-stuffs and chemicals, but special attention is to be devoted to the manufacture of fast dyes for textile manufacturers and dyers throughout the country. Scottish Dyes, Ltd., was initiated by Messrs. Morton, of Carlisle, the proprietors of "Sundour," which has had a rapid success, along with other dyes, since the war. For many years Messrs Morton had made a speciality of the manufacture of fast-dyed textile fabrics, importing the colouring materials from Germany, and have now an important dye-making department at Carlisle, under the name of the Solway Dyes Company. As soon as possible the extensive Grangemouth factories will be in full working order.

CHEMICAL WORKER'S TRAGIC DEATH.—Mr. Isaac Bradley, the Birmingham coroner, held an inquest on Friday of last week relative to the death of Leonard Baden Gittos (19), carbolic acid plant assistant, of Witton Road, Aston, following an accident at the works of Josiah Hardman, Ltd., chemical manufacturers, Aston Church Road. The youth, who was on night work, had to inspect certain taps in connection with the plant, which controlled the water supply, and also to examine a pipe passing over a scrubber. To do this he had to climb baulks of timber, loosely placed, with intervals between, forming steps. He carried a Davy lamp. At 10 p.m. on Wednesday it was found that he had fallen into a vat of boiling water. He was alone, and managed to crawl out by himself, his shouts afterwards attracting attention. At the hospital the young man said he slipped from the planks into the vat. The lamp was found in the vat next morning. Horace Clarke Boucher, works manager, stated in reply to Mr. Hepburn (H.M. Inspector of Factories) that it had not occurred to him that it was dangerous for a person to stand on planks to get to the vat. A fixed platform, railed round, would now be erected. Factory Act inspectors had said nothing about the absence of railings. Mr. Hepburn replied that it was not for firms to wait until a factory inspector said something ought to be done. Those who had control of works should see that Government regulations were carried out. A verdict of "accidental death" was returned. Mr. Baker expressed regret on behalf of the employers at the accident, and stated that he did not know whether hot water would be regarded as a dangerous mixture under the rules governing chemical works.

NATIONAL ASSOCIATION OF INDUSTRIAL CHEMISTS.—The Council of the London Section of the National Association of Industrial Chemists promoted a dinner and musical evening at the Ship Restaurant, Charing Cross, on September 27. In spite of the difficulties created by the railway strike, there was a fairly good attendance of members and friends, presided over by Mr. H. S. F. Rhodes, Chairman of the London Section Council. Mr. Rhodes emphasised the necessity of federation between the various organisations of scientists, and pointed out that the members of the council had always been strongly in favour of federating, having twelve months ago passed a resolution recommending federation of the N.A.I.C. with other associations which had similar aims and objects. Mr. F. N. Harrap, secretary of the section, gave a short resume of the history of the section, and pointed out the advisability of adopting a policy of decentralisation, by the institution of branches, similar to that already started in Dartford. Mr. Harrap explained that the question of registration as a trade union had been decided, and the association would probably be registered within a few days. With regard to the question of federation with other scientific bodies, the speaker pointed out that the Federation of Technical and Scientific Professional Associations had already been formed, with Mr. A. C. J. Charlier (President of the N.A.I.C.) as president. The Federation, consisting of professional associations operating as trade unions, would meet on October 18 to fix the rules and constitution. In conclusion, the secretary appealed to the members to maintain their interest in the association, and to realise that progress for the first two or three years, whilst the association was being organised, must necessarily be somewhat slow.

BEET SUGAR.

ACCORDING to the *Foreign Trade Record* of the National City Bank of New York, the United States will this year take second rank among the nations as a producer of beet sugar. While this new and greatly advanced rank is in part a result of the political rearrangement of the beet-sugar-producing areas of Europe, coupled with a marked falling-off in production of beet sugar in that continent, it at least is interesting, and, at the same time, illustrative of the growth of beet-sugar production in the United States. At the beginning of the war, the *Record* continues, the United States held only fifth rank among the beet-sugar-producing countries of the world, and, in fact, produced but about 8 per cent. of the beet sugar of the world. The marked falling-off in the European product, coupled with the slight increase in the production in the States, brought its share of the world's beet-sugar production to about 16 per cent. last year, with a prospect that the crop of the current year will be larger than that of last year, and form a slightly larger percentage of the world's total output. Latest estimates by sugar authorities indicate that the crop in the current year will be larger than that of last year, but may fall slightly below that of the high record of 1916.

While this new rank which the United States holds among the sugar producers of the world is due in part to increased production on the one hand and the decreased production in Europe, it is also due in part to the recent events which have established new political divisions within the beet-sugar areas of Europe. Prior to the war, Germany held first place as a beet-sugar producer, Austria-Hungary second, Russia third, France fourth, and the United States fifth. As a considerable part of the production of Austria-Hungary occurred in the section now designated as Czecho-Slovakia, and a considerable proportion of that of Russia occurred in the areas now known as Ukraine and Poland, the rank of European production by political divisions has been entirely disarranged, and it seems probable that no one of the European countries except Germany will this year produce as much beet sugar as does the United States. Latest estimates put the production of Germany at about 1,400,000 tons, while that of Czecho-Slovakia, Ukraine, and Poland will apparently fall materially below that of the United States, which for the current year will range between 700,000 and 800,000 tons.

Sugar-beets now produce only about 25 per cent. of the sugar of the world, as against 50 per cent. in 1911 and 65 per cent. in 1900 and 1897. Normally, beets supply about one-half of the sugar of the world, their large percentage in 1900 and the years immediately preceding being due to the very small production of cane sugar in Cuba during and immediately following her war with Spain. With the return to normal production of cane sugar in Cuba the share which beets were producing of the world's supply dropped from 65 per cent. to 50 per cent. in 1911 and 1913, 47 per cent. in 1914, 44 per cent. in 1915, 35 per cent. in 1916, 33 per cent. in 1917, 28 per cent. in 1918, and is estimated at about 25 per cent. in 1919, this change being due in part to the falling-off of beet-sugar production in Europe, and in part to the increased production of cane sugar produced in Cuba, Porto Rico, Hawaii, the Philippine Islands, and Java.

The world's production of sugar in the current crop year will probably be about 37,000,000,000lb., against

42,000,000,000lb. in 1914, and the share produced from beets about 25 per cent., as against 47 per cent. in 1914.

DYEWARE IMPORTS.

STRONG protest against restrictions on dye imports was made at a meeting of the Dewsbury (Yorks.) Chamber of Commerce. The President, Mr. Medley, observed that eleven months after the cessation of hostilities on the Continent the textile manufacturers in Yorkshire were still experiencing the very greatest difficulties owing to their inability to get dyewares, particularly bright colours which were fast to milling. They (the manufacturers) were running from pillar to post, and were then limited to the ridiculously small quantities that were to be obtained when the agents of the Swiss firms divided their supplies among the many manufacturers who were clamouring for colours. It was really absurd that a great industry like the woollen industry should be handicapped in that manner.

With the exception of sulphur black, synthetic indigo, chrome yellow and brown, such as could be obtained during the war, he was advised that the local manufacturers were still dependent upon Swiss firms for 75 per cent. of their total requirements. It was not a question of obtaining cheap dyewares so much as an adequate supply of the absolutely necessary colours. Many months ago a licensing committee was appointed by the Board of Trade, but there was no representative of the woollen trade on it. Up to now he had not heard of any licences being granted to import dyestuffs into this country; yet everybody understood that the committee had to control the arrangements for the supply of dyestuffs from Germany and Switzerland. Why, if these dyes had come from Germany, should the Yorkshire manufacturers of woollen goods not be placed on an equivalent level with the Americans?

The American Government, he added, had issued an order allowing the import from Germany of a six months' supply of dyewares. To a large extent the British woollen industry was being held up, though it was particularly essential to the heavy woollen trade that there should be an adequate supply of colours, bright in shade, fast to light, and capable of withstanding heavy milling. The anxiety of the woollen manufacturers was lest they should be compelled to fall below the pre-war standard of efficiency, or suffer in comparison with any foreign production. Whilst hoping that British producers of dyestuffs would be able to meet the needs of the trade with colours equal to foreign production, he was of opinion that something must be done in the meantime, and that quickly, to relieve the difficult situation.

The meeting finally resolved to bring the whole subject to the notice of the Board of Trade and the Associated Chambers of Commerce.

PREPARATION OF INDICAN FROM NATURAL INDIGO.—The Agricultural Research Institute of India publishes a new method for the preparation of indican. The indigo leaves are boiled twice with water, and the extract is then mixed with freshly slaked lime and filtered; the precipitate contains most of the gums and tannins. The filtrate is concentrated by evaporation, and then saturated with carbon dioxide gas in order to remove the lime. The liquid is filtered again, and concentrated to a syrup by evaporation. The extract is next mixed with acetone, the acetone extract separated and washed, and then the acetone is distilled off to a small volume. This is next mixed with ice, which causes crystals of indican hydrate to separate out. These may be further purified by recrystallisation from benzene.

LEGAL INTELLIGENCE.

Dealings in Chemicals.

At the London Bankruptcy Court on Tuesday before Mr. Registrar Meilor, the public examination was held of Albert Edward Smith, described as of 2, St. John's Terrace, Westbury Road, Forest Gate, and carrying on business at 18, Beer Lane, E.C.3. The statement of affairs filed by the debtor showed gross liabilities amounting to £3,528 18s. 6d., of which £1,528 18s. 6d. was due to unsecured creditors; assets nil. The receiving order was made against the debtor on March 6 last on the petition of a creditor, the act of bankruptcy being the failure of the debtor to comply with the requirements of a bankruptcy notice.

In reply to questions put by the Official Receiver, debtor stated that from 1907 until 1914 he was employed as clerk or book-keeper with different firms of chemical merchants in the city. From August, 1914, until April, 1916, he served in the Cyclists' Battalion of the Essex Regiment, and was then discharged from the Army. From April until August, 1916, he was employed as clerk by a chemical firm in the city. In August, 1916 while still in employment he carried on business from his mother's address as a chemical merchant, but subsequently he opened an office at 18, Beer Lane, E.C. He closed it however after a time because he found it was of no use to him, and since then has conducted his business from his mother's house at Forest Gate. He had paid all the liabilities incurred at Beer Lane. In the spring of 1916 he contracted to buy 310 tons of soda ash at £6. 10s. per ton from the Vulite Company. He had no capital at the time but he arranged to sell the goods at £13. 10s. per ton for export. Although he was employed as a clerk to a chemical firm, he managed to enter into this arrangement through meeting a traveller of the Vulite Company. Subsequently the Vulite Company refused to let him have the goods, because they could not let them go for export. They had purchased the goods from Messrs. Brunner Mond and Co., and the latter would not allow them to be sent abroad. If the Vulite Company had allowed the goods to have been sent abroad they would have been refused any further supplies. He brought an action against the Vulite Company for breach of contract with the result that he was awarded 3s. damages, and each side had to pay their own costs. He took the case to the Court of Appeal, when the judgment was confirmed. The costs of the Appeal amounted to about £170, which he paid out of his savings. The people to whom he had sold the goods agreed to accept half the damages he obtained, consequently they received nothing.

In October, 1917, he entered into a contract to sell 200 tons of caustic soda at £31. 10s. per ton. As soon as he obtained the order he entered into a contract to purchase the caustic soda at a price which showed him a substantial profit. He did not sell the caustic soda before he had actually obtained an option to purchase it. His profit on the transaction was about £4. per ton, to which had to be added the cost of the casks. He contracted to purchase the caustic soda from Messrs. Luke and Bailey, and he had arranged to sell same to the Northern Dyers and Chemical Company. He could not provide the money to pay for the caustic soda, and the Northern Dyers agreed to pay the money into his banking account subject to its being released when the goods were received. He could only obtain the caustic soda from Messrs. Luke and Bailey in small lots of two or three tons at a time, and as he could not touch the money paid into the bank by the Northern Dyers, he entered into an arrangement with the Immediate Transportation Company, under which they agreed to pay for the caustic soda as received. Afterwards the Northern Dyers refused to accept the goods on the ground that it was not up to sample. The stuff he tendered to them was exactly the same as the sample. The Northern Dyers Company brought an action against him for breach of contract and he put in a counterclaim for loss of profit. At that time the market price had gone down to about half, and debtor alleged that that was the real reason why the goods were rejected. He understood from his solicitors that he had obtained judgment against the Northern Dyers, but afterwards it transpired that the matter went to arbitration under which the Northern Dyers were awarded £897. damages. He subsequently cancelled the contract with Messrs. Luke and Bailey on the ground that they had sent the goods along in such small lots. The Immediate Transportation Company were creditors for £681. for money advanced. He did not know whether they still held the caustic soda.

Subsequently he contracted to sell a quantity of soda ash at £11. per ton. He purchased the goods at £10. 17s. 6d. per

ton, which left him a profit of 2s. 6d. per ton. He made a verbal contract with the vendors, but had no written contract, and eventually they declined to allow him to have the goods. He alleged it was because the price had in the meantime gone up to £12. per ton. An action was brought against him by Messrs. Grant, Hughes, and Co., to whom he had agreed to sell the soda ash, and they obtained judgment against him for £251.

His justification for entering into these contracts was that he thought he could carry them through. He was 26 years of age and the knowledge he had picked up whilst in the employment of different firms, justified him in dealing with these large amounts of chemicals. In February of this year he entered into contracts to buy a large amount of glue. He had no banking account at the time. He had borrowed money from his wife from time to time before he was married. In September last year he contracted to buy certain houses at Peckham for £1,900. He borrowed £2,000. from a Mr. Macdonald, in order to complete the purchase. He represented to Mr. Macdonald that the property was costing £3,000., and he told that gentleman he would give him a share of the profits he obtained from a transaction in soap. He had arranged to buy 100 tons of soft soap at £25. per ton and thought he could sell it at £35. per ton. He did manage to sell some at £35. per ton, but the remainder of the contract was cancelled.

The examination was eventually ordered to be closed.

Failure in the Chemical Trade.

At the Leeds Bankruptcy Court on Tuesday, before Mr. Gillespie (Registrar), the examination was resumed of Edwin Fredk. Heesch, lately residing at 158, Woodsley Road, formerly carrying on business at 212, Wellington Street, as a manufacturer's agent, now residing at 59, Clarendon Road, and carrying on business at Stansfield Mill Yard, 77 and 79, Kirkstall Road, as oxy-acetylene welder and chemical manufacturer, under the style of "The Gatap Company."

Debtor estimated his gross liabilities at £1,013. 19s. 6d., of which £924. 5s. 1d. is expected to rank for dividend, and the total available assets amount to £155. 15s. 7d., leaving a deficiency of £768. 9s. 6d. He ascribed his failure to "bad trade and losses in the chemical business owing to faulty manufacture." The debtor described himself as "a Dane by birth and German by conquest." He came to England in 1891, and in 1896 commenced business as a manufacturer's agent, dealing mainly with textile machinery made in Germany.

The examination was again adjourned for further accounts to be filed.

Brunner, Mond and German Patents.

On Tuesday an application was made to the Controller of Patents (Mr. H. Temple Franks) on behalf of Brunner, Mond, and Co., of Wilmington, Northwich, for a licence in respect of two German patents owned by the Badische Anilin und Soda Fabrik for the manufacture of ammonia.

It was stated, on behalf of the applicants, that the manufacture of ammonia was very necessary for explosives, and also in peace time for fertilisers, and that applicants were prepared to spend half a million on experimental plant for working these patents.

The Court intimated that the grant of these licences would be recommended.

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Aramo Copper Mines, Ltd.—Meeting of creditors, 2, Metal Exchange Buildings, E.C., October 3.

Cogschultze Ammunition and Powder Company, Ltd.—Resolved July 30, confirmed August 15: That the company be wound up. F. J. Livesey, 42, Essex Street, Strand, W.C., chartered accountant, liquidator. Meeting of creditors at liquidator's, October 2.

Henrite Explosives, Ltd.—Resolved July 30, confirmed August 15: That the company be wound up. F. J. Livesey, 42, Essex Street, Strand, W.C., chartered accountant, liquidator. Meeting of creditors at liquidator's, October 2.

San Miguel Copper Mines, Ltd.—Resolved August 29, confirmed September 17: That the company be wound up. E. Johnston, 295-8, Salisbury House, E.C., liquidator. Claims to liquidator by November 8.

CORRESPONDENCE.

Malachite Green Crystals.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir, The attention of this Association has been drawn to several instances on the Dyestuffs Licensing Sub-committee refusing to grant licences for the importation of malachite green crystals of American origin. The reason given for the refusal is that the committee "understand this product is now available from British sources of supply." It is, however, significant to note that the committee have ignored requests for information as to the names of British manufacturers who can, in fact, supply, and our correspondents have endeavoured, without success, to obtain supplies from such leading British firms as British Dyestuffs Corporation, Ltd., Clayton Aniline Company, Ltd., and L. B. Holliday and Co., Ltd.

I would therefore like to issue, through your columns, a public invitation to any British manufacturer who can supply to communicate with this Association, in order that I may put him in touch with our members who are wanting the goods. The lack of supplies means that expensive plant in this country has to stand idle. The dye in question is essential to the manufacture of finished silk goods, woollen goods, etc.; it is indispensable for "topping" and brightening cotton goods, and is of the first importance in the leather, jute, pigment, and other trades.

The Government have asked the country to increase its export trade, and, at the same time, we find one of their Departments not only hindering the manufacturer, but apparently wilfully and knowingly impeding the production of goods of a standard that will favourably compete in foreign trade.

This Association invites communication from firms who are suffering through the present unsatisfactory arrangements, and who object to disclosing the whole of their private business to an individual firm camouflaged under the official title of the "Central Importing Agency."

I would also add that the policy of this Association throughout is to foster British production. We would not for one moment urge that licences should be granted for the importation even of Allied dyestuffs where satisfactory British supplies are available at anything approaching a reasonable figure.—Yours, etc.,

THE BRITISH CHEMICAL TRADE ASSOCIATION.

O. F. C. BROMFIELD, Asst. Sec.

80, Fenchurch Street, London, E.C. 3,
October 6, 1919.

Chemists at Gretna Factory.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—If all that "Morrison" describes in his letter to your issue of September 20, of the wholly foolish and insane conduct of the Gretna "chemists" (the inverted commas are mine), be true, I am not surprised at the feeling of contempt, tempered somewhat by sorrow and pity, with which he was moved. He is generous to these unqualified "chemists" (again the inverted commas are mine) in crediting them with being skilled workers on an equality with the recognised and unequivocal trades of plumber and lead-burner; and chemists of recognised qualification will be gratified to read that "Morrison," having a very proper sense of discrimination, "knows and honours the value of the true chemist."

All this kind of thing, sir, only emphasises, if I may say so, the unfortunateness of the fact that as yet the term "chemist," except as applied to pharmacists, has not been restricted by statute to men and women of (1) good character, (2) sound general education, (3) proper systematic training in chemistry and collateral sciences in recognised institutions, (4) hallmark qualification; but is used by all and sundry who perform any routine operation connected with manufacture in a chemical works. Such men are artisans pure and simple, skilled to perform a limited number of practical operations. In short, are highly worthy trade workers like any other workers at a trade, and are not to be confused with the body of fundamentally and systematically trained qualified professional chemists.—Yours, etc.,

Dartford, October 6, 1919.

Laboratory Glassware.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—Kindly permit me a short space in your valuable journal concerning the chemical glassware used in laboratories. We find the glass well blown, but the annealing generally bad, whether bought from Scotch or English firms. Flasks are often found when required for use to have cracked whilst in the cupboard. These cracks are principally found around the necks where the rounding-off occurs, and a complete ring of glass drops off, showing that no annealing has been attempted. Manufacturers will do a good service to chemists if they would give annealing far more serious attention than is being given at present. I was using two Soxhlet extraction apparatus, and found each one had internal strains, resulting in cracks which completely spoiled my experiment and wasted a lot of precious time. Unless British manufacturers can produce a reliable annealed apparatus we shall be obliged to place our orders with foreign makers.—Yours, etc.,

P. G. ABRAHAM.

42, St. John's Road, Maindee, Newport, Mon.,
October 1, 1919.

The British Chemical Trade Association.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—We notice in your last issue a considerable amount of correspondence from the British Chemical Trade Association. It would be interesting to know who this Association represents, and how many of its members were recognised dealers in chemicals before the war.

The Board of Trade, apparently, are in doubt as to whether the Association is in any way qualified to represent the chemical trade in London.—Yours, etc.,

London, September 30, 1919.

OUR BOOK SHELF.

THE MANUFACTURE OF CHEMICALS BY ELECTROLYSIS. By A. J. Hale, B.Sc., F.I.C. London: Constable and Co., Ltd.; 6s. net.

Increasing interest in electrolytic processes warrants an extension of technical literature on the subject. The present volume is an important addition, covering as it does, although briefly, general principles and modern developments in diverse directions. To enumerate all its contents would take up more space than we can spare; very important features, however, are the sections dealing with per-salts, in which also are contained brief references to hydrogen peroxide from persulphuric acid, etc. Hydrosulphite of soda is another feature of wide interest. Other sections are the electrolytic reduction of organic compounds and the oxidation and substitution of organic compounds. References to English and foreign patents and to sources of literature are enumerated throughout. A really good book, which must stimulate study in new channels.

THE HYDROGENATION OF OILS. 2nd edition. By Carleton Ellis, S.B. London: Constable and Co., Ltd.; 36s. net.

A highly practical book, dealing with the operations involved in all variations of this important process. The author carefully discusses and illustrates every modification worthy of attention. As catalysts, both base and rare metals receive detailed treatment. Edible hydrogenated oils, uses of hydrogenated oils, the hydrogenation of petroleum, and hydrogen production—all form lengthy sections admirably treated. As from time to time we receive frequent inquiries for text-books on this subject, readers generally will do well to make a note of this highly useful volume.

CHEMICAL REAGENTS. By Dr. C. Krauch. (Second English edition revised and enlarged by H. B. Stocks, F.I.C., F.C.S.). London: Scott, Greenwood and Son, 17s. 6d. net.

The second English edition of this well-known work must continue its career of utility. Purity in reagents is the first law of the laboratory, and a book which deals, as this one does, with probable impurities, their detection, quantitative estimation of the reagent, uses and storage, and also descriptions of commercial varieties, etc., must cover much ground. That the present volume deals with these very important matters very ably and extensively is but a fair need of praise. All the new reagents such as dimethyl glyoxime, nitron, benzidine, etc., have been added, and are well treated.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Nitrate of Soda.—The position of the nitrate industry, after being so devoid of interest, has suddenly become full of incidents worth recording. As mentioned recently the Producers' Association in Chili after "fixing" the price of ordinary nitrate at 10s. 1d. per quintal f.o.b. and then threatening to reduce it to 8s., sold 500,000 tons at 9s. for delivery October to March. The sale of a further 250,000 tons on the same terms is now announced, and offers for a similar quantity being refused, the price has now been "fixed" at 9s. 4d. for October-November, and 9s. 6d. for December shipment. These large transactions *en bloc* are the more satisfactory in that before the war, when there was a "free market," sales were made piecemeal, the principle buyers being the large German firms, now for obvious reasons no longer taking the same important part in the trade; it would therefore, as we have already said, be interesting to know the names of the present gigantic purchasers. Curiously enough, considerable sales are reported at £22. per ton, c.i.f. Continental outports, that figure being well below the parity of nitrate bought at 9s. per quintal with freight at the rates recently quoted. Even more surprising is the announcement that the British Government have just sold at from £17. 10s. to £18. per ton the balance of their stock of nitrate in this country, costing many pounds more. We shall have occasion to revert to the matter, meantime trusting that our friends in the chemical trade have participated in the bargain. The Chilean companies standing aloof from the Association have now joined it, leaving the American and German *oficinas* outside it, and the only obstacles in the way of a gradual rehabilitation of the nitrate industry are the scarcity of tonnage and the prohibitive price of the fertiliser. Neither of these can be ignored. The September shipments from Chili were only about 44,000 tons. Details will appear next week.

Italian Fertiliser Notes.—Information from Italy shows that there is an active demand for superphosphates which is growing in volume, even in those districts where it was thought there would be a falling away owing to the agrarian troubles. It is observed also that the goods are being despatched with commendable regularity. As to basic slag it appears that there is not much that is new. Italy is waiting to know what the French Government are going to do with respect to the permission to export the merchandise in response to the advances made by the Italian Government. In any case, however, it is quite understood that the quantity of slag that will be available must be very limited. The position is very difficult in respect to sulphate of ammonia. The home production of course, is known to be exceedingly small and altogether unequal to the requirements of Italian agriculture; whilst, on the other hand, there appears to be no prospect of being able to import any from England; nor yet facilities for importing it from America. Such parcels of sulphate of ammonia as are available are quoted at 130-135 lire per quintal. The prospects of having potassic salts from Alsace are also very clouded. There has been great delay in deliveries, and orders in arrears will occupy the transport services over a considerable time.

Sulphate of Ammonia.—Deliveries of sulphate, as of all other fertilisers, have been directly and badly impeded, and trade is at a very low ebb. Prices are, of course, fixed until next year, and the export figure is given nominally as round about £25. A big bull point for this fertiliser is that farmers have become thoroughly convinced of the value of the material. Propaganda in the years preceding the war found fruition during the necessities of the war period, but even now propaganda is not being neglected and the farmer is all the time being advised by means of leaflets and "reason why" posters. He has no chance, therefore, of missing the sulphate of ammonia lesson. Impeded deliveries now would only mean very much bigger deliveries by and by, and the material seems likely to reach in the current year a level of popularity never before touched. Whilst high prices remain, of course, the biggest possible trade will not mature, and this can be said whilst at the same time the necessity of the high prices is realised. The American production is reported to be still growing, although here again strike troubles may have a temporary but important adverse effect.

Potash.—Labour and transport troubles apart, there would appear to be signs of a further improvement in the supply of potash manures, but these are still by no means bulking largely. The movement on the part of the American potash producers to secure some measure of protection for their

industry is being regarded with a good deal of suspicion by the farmers generally in the United States, especially as someone has been trying to stampede the farmers with the cry that their potash, if all home-produced, will cost them three times the price of imported German potash. In this country potash is required for many districts very obviously.

Slag and Superphosphate.—Taking conditions into account, the business in basic slag is fairly active. The increased make looks like again being checked, however, and this suggests higher prices. One thing that is certainly being driven home to the farmer again just now is the need for early ordering if he desires to get his material in hand while it can still be applied to the ground. The time to apply basic slag with the best effects is autumn or early winter, and farmers have always to remember that the higher the percentage of solubility, the greater will be the value of the efficacy of the manure. Superphosphates show little change, but demand over the recent period has exhibited signs of improving. Supplies, however, are not viewed with placidity; the raw material and the shipping position could do with a lot of improvement.

Other Fertilisers.—East Indian bonemeal is as highly priced as ever at about £15. for good class material, and inferior sorts ranging down to about £9. Dried blood, meat meals and tankages can be taken at about the figures given recently here. Fish guanos sell well according to analyses where offered, but there is no trading in Peruvian guano now being reported. The scheme whereby the Nitrogen Products and Carbide Company are going to amalgamate with the Alby United Carbide Factories was held up for a long time owing to the disinclination of the Norwegian Government to meet the companies in a friendly spirit. The scheme is now being proceeded with and meetings of the shareholders are due in the middle of this month. This should be the prelude to a period of effective manufacture and overseas business.

Barcelona Fertiliser Quotations.—The following prices are quoted for chemical fertilisers in Barcelona:—Nitrate of soda, 25 per cent. and 15-16 per cent. nitrogen, 72 pesetas; sulphate of ammonia, 20-21 per cent. nitrogen, 88 pesetas; sulphate of potash, 90-95, equal to 30/32, 118 pesetas; mineral superphosphate of lime, 13-15 per cent. soluble phosphoric acid, 20 pesetas; ditto, 16-18 per cent., 25 pesetas; bone superphosphate, 18-20 per cent. soluble phosphoric acid and 1-2 per cent. nitrogen, 34 pesetas. These quotations are subject to variation according as the parcels dealt in may be under or over a ton, all per unit of 100 kilogrammes.

Norwegian Agency for Alsace-Lorraine Potash.—According to a circular issued, the Norwegian Nitrate Company has acquired the general agency for the Alsace-Lorraine potash mines to cover all Scandinavia and Finland. The importance of this transaction is seen in that both Norway and Finland each consume about 200,000 tons of potash per annum, whilst Sweden and Denmark take 60,000 tons each.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

It will be next week before there is a complete resumption of operations in this district, but the collieries and by-product coke ovens are already working, and their output will be absorbed as soon as the furnaces on low phosphorus and ordinary brands of iron are in blast again between Workington and Carnforth. At mid-week there were only two furnaces in full draught, but it is believed that all twenty-four furnaces will be working to-day. The restarting of the rail mill at Workington next week assures the maintenance in blast of the furnaces on ordinary iron which consume all the coke made at the Cumberland by-product coke-ovens. It is too early yet of course to judge how business will develop in the hematite pig-iron trade, but there is just a possibility that if the country settles down to work and confidence is re-established the demand for iron may be greater than it was a fortnight ago, and in that case additional furnaces may be blown in. Certainly until that does take place the ovens must remain working at only two-thirds of their capacity.

BUSINESS NOTICE.—The business of Messrs. Donald Campbell and Co., oil, wax, tallow, etc., merchants, of 10, St. Mary Axe, E.C.3., has been converted into a limited company with a capital of £500,000 of which £450,000 has been issued and fully subscribed. The company takes over all contracts and all liabilities.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

September 22nd to 27th (inclusive).

- Conducting a Liquid and a Gas Soluble in Said Liquid Through Closed Cycle of Thermal Operations. Beadle, C. H. 23,491.
 Production of Glycerine by Fermentation. Cocking, A. T.; and Lilly, C. H. 23,644.
 Alkali Chromates and Iodine. Datta, R. L. 23,375.
 Direct Oxidation of Ammonia. Duparc, L.; and Urfer, C. 23,505.
 Apparatus for Detecting and/or Controlling Mixture of Liquids and Solutions. Empson, A. W. 23,478.
 Method of Cooling or Allowing to Crystallise Fatty Emulsions. Erstev, K. 23,585.
 Recovery of Tin from Tin-pot Skimmings and Chloride of Zinc as By-product. Evans, A. J. and H. D. 23,318.
 Fertilisers. Fellowes, E. N.; and Hyatt, W. H. 23,730.
 Pectisation of Condensation Products of Phenols and Aldehydes. Jaloustre, L. A.; Kheifetz, Z.; and Warchavsky, M. 23,379 and 23,380.
 Treatment of Mineral Oils, etc. Knibbs, N. V. S. 23,515.
 Manufacture of Complex Silver Salts of α -amido Acids. Napp, H. R. (Hofmann-La Roche and Co.). 23,372.
 Colouring-matters. Pope, Sir W. J.; and Scottish Dyes, Ltd. 23,799.

September 29th to October 4th (inclusive).

- Treatment of Metal-bearing Ores, etc., and Recovery of Constituents Thereof. Ashcroft, E. A. 23,960.
 Granulating Cyanamide. Barbé, L. L. J. 24,039.
 Conversion of Fatty Acids or Oils or Fats Containing Free Fatty Acids into Glycerides. Bolton, E. R.; and Lush, E. J. 23,957.
 Zinc Chloride. Burgess Laboratories, C. F. 24,129.
 Oxygen Compounds of Sulphur. Clayton, T. A. 24,040.
 Rotating Colour Mixing or Blending Devices. Clifton, W. E.; and Ewart, J. S. 24,270.
 Pulverising or Atomising Liquids. Constantinesco, G. 23,880.
 Manufacture of Painting, Priming, etc., Compositions. Emulsion Aktieselskabet; and Schou, E. 23,964.
 Ore-concentrating Machine. Gasche, F. G. 24,166.
 Drums for Drying Materials. Gerlach, A. 24,228.
 Drying-apparatus. Higginbottom, E. 24,250.
 Raising Liquids. Higginson, J. 24,111.
 Drying-apparatus. Imray, O. (Secord, Peters, and Paterson). 24,048.
 Conversion of Wash from Distillery into Fertiliser. Kestner Evaporator and Engineering Co.; and Reavell, J. A. 24,176.
 Stabilising Nitro-cellulose. Laan, B. van der. 24,119.
 Disintegrating, Spraying, or Vaporising Liquids. Lang, A. A. D. 24,209.
 Ammonium-nitrate Explosives. Muller, E. 24,120.
 Enriching Poor Phosphates. Poupart, C. 24,187.
 Petroleum Jelly. Rütgerswerke Akt.-Ges. 24,047.
 Cellulose Acetate. Scott, J. L.; and Tulloch, T. G. 24,122.
 Solder for Aluminium and Its Alloys. Shortland, H. 24,163.
 Hydro-extractors. Singleton, W. C. 23,819.
 Phenolic Resins or Esters. Soc. Coralex. 23,958.
 Aliphatic Nitrates. Wilde, P. R. de. 23,881.
 Determining Composition of Gases. Williams, A. and L. D. 24,005.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 6d. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.

1917.

- Solutions of Cellulose or Material Containing Cellulose. Bloxam, A. G. (Zellstoffabrik-Waldhof). 14,806. 132,815

1918.

- Oxidising Ammonia to Form Oxides of Nitrogen and Nitric Acid. Jones, L. C.; and Parsons, C. L. 7,221. 132,551
 N-monoalkyl Derivatives of Certain Aromatic Compounds. Lapworth, A.; and Levinstein, Ltd. 9,710. 132,555
 Acetaldehyde. Matheson, H. W. 10,070. 132,557
 Acetic Acid. Matheson, H. W. 10,071. 132,558
 Recovering Mercury from Mercury Sludge. Matheson, H. W. 10,072. 132,559
 Oxidising Mercury. Matheson, H. W. 10,073. 132,560
 Alkali Percarbonates. Deutsche Gold-und Silber-Scheide-Anstalt vorm. Roessler. 10,282. 116,903
 Desulphurisation of Zinc Sulphide Ores. Rigg, G. 11,588. 119,223
 Burner for the Oxidation of Ammonia. Maxted, E. B.; and Smith, T. A. 13,037. 132,571
 Treating Peat for Obtaining Carbonaceous Material for Decolourising Purposes. Leadbeater, J. W. 13,111. 132,572
 Furnaces for Distillation of Coal, Shale, and Other Like Substances. Anderson, F. A.; Deacon, M.; and Brady, N. P. W. 13,221. 132,576
 Purification of Sewage and Other Liquids. Jones, W.; and Jones and Attwood. 13,379. 132,581
 Concentrated Nitric Acid. Norsk Hydro-Elektrisk Kvaestofaktieselskab. 15,241. 120,378
 Cyanamide. Gross; and Bouchardy, F. 15,540. 132,622
 Production of Nitrates by Means of Bacteria. Thorssell, C. T.; and Lundén, H. L. R. 15,667 and 15,669. 132,625 and 132,626
 Sulphatising Ores. Aarts, J. G.; and Aarts, C. J. G. 15,830. 119,867
 Recovering Unoxidised Sulphur-dioxide in the Contact Manufacture of Sulphuric Acid. British Dyes, Ltd.; Turner, J.; and Davidson, W. B. 17,869. 132,661
 Recovering Potassium from Potassium-bearing Silicates. Granel, A. 21,808. 132,693

- Purification of Sewage and Other Liquids. Jones, W.; and Jones and Attwood. 7,104. 132,826
 Potassium Permanganate. Dreyfus, C.; and Bloch, J. J. 13,793. 132,842
 Extracting Potash from Potash-bearing Minerals, and the Manufacture of the Residual Products of Such Method of Conversion into Cement. Auden, A. C. 15,431. 132,855
 Detanning Chrome Leather for the Manufacture of Glue and Like Products and Recovery of Chrome Compounds. Lamb, M. C. 15,496. 132,864
 Production of Nitrates from Ammonia, Ammonium Compounds, or Organic Nitrogen Compounds by Means of Bacteria. Thorssell, C. T.; and Landen, H. L. R. 15,668 and 15,671. 132,882 and 132,883
 Evaporating Liquids. Morterud, E. 15,959 and 15,961. 132,893 and 120,205
 Continuous Process for the Production of High-Strengths of Fuming Sulphuric Acid. British Dyes, Ltd.; Turner, J.; and Davidson, W. B. 17,872. 132,923
 Recovery or Separation of Colloidal Matter from Liquids. Barber, T. W. 19,888. 132,947
 Fuel Oils. Tinker, F. 21,588. 132,960

1919.

- Concentration of Sulphuric Acid. Howorth, F. W. (Norsk Hydro-Elektrisk Kvaestofaktieselskab). 1,637. 132,704

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

- Fuel Oils. F. Tinker, Erdington, Birmingham. British Patent, 130,699, of 1918.

A fuel oil containing both mineral oil and tar or tar oils containing pitch is obtained by adding to the tar, etc., before it is mixed with the mineral oil, a third ingredient or intermediate oil which is miscible with each of the other ingredients and which is intermediate of them in its chemical composition and surface tension. Usually, an intermediate oil is intermediate in specific gravity also, as it is found that the surface tension and specific gravity increase with the proportion of carbon, oxygen, nitrogen, and sulphur in the oil. In one method of making an intermediate oil, a mineral oil is oxygenated. For example, a shale oil of a specific gravity of 0.89-0.90 is heated to 300° C., and air is blown through it for three-four hours until the product is soluble in tar and has acquired the necessary surface tension. In a second method, asphaltic oils, such as Mexican oils, are stripped of the lighter and medium fractions, thus removing the oils having a high hydrogen-content. In a third method, oils such as Borneo oils having the requisite hydrogen-content are stripped until

the requisite surface tension is obtained. In a fourth method, naturally occurring intermed. oils are used. If the surface tension of these oils is slightly too low, as in the case of oils from Trinidad and Texas, or too high, as in the case of creosote, heavy asphaltic oils and asphalts, and oils from sulphurous shales, the surface tension is adjusted by blending. The tars, etc., employed include dehydrated tar alone or mixed with pitch, and creosote oil in which pitch has been dissolved. The tar, mineral oil, and intermediate oil are preferably used in equal proportions, and any solids are separated by heating to 85-90° C. and afterwards settling or filtering.

Ammonia. E. B. Maxted, Walsall, Staffs. British Patent, 130,023, of 1917.

Ammonia is produced by subjecting a gas mixture consisting of, or containing in substantial proportions, nitrogen and hydrogen, at an elevated pressure, to the action of an electric arc, preferably of high tension, the gas mixture produced being rapidly cooled, for instance, by direct or indirect contact with water or a cooler gas current. The temperature to which the gas is heated by contact with the arc is preferably 2,000° C. or higher, and a suitable pressure is from 50 to 100 atmospheres. In the apparatus described a nitrogen-hydrogen mixture, compressed by a compressor B and circulated by a pump D, is subjected in a reaction chamber A to the action of an arc formed between electrodes C¹, C²; the gas mixture produced passes

through a non-conducting water-cooled tube E and a cooling-coil F to a chamber G, in which the ammonia is eliminated by refrigeration or absorption, the unconverted gas being recirculated by the pump D. Fresh gas, to compensate for that transformed into ammonia, is passed into the apparatus through the compressor B. The cooling-coil F may be omitted, the gas mixture being led directly into water in the absorber.

Cellulose Acetate Solutions. Cellon, Ltd., Tyrer and Co., P. H. Chambers, and G. T. Feasey, London. British Patent, 130,402, of 1918.

Cyclohexanone, cyclopentanone, or other cycloketones or alkyl or aryl substitution derivatives are added in small proportions to cellulose acetate solutions for use as aeroplane dopes, etc. The proportion is less than the amount of cellulose acetate contained in the solution.

Extracting Metals. F. M. Wiberg, Bergsskolan, Falun, Sweden. British Patent, 130,334, of 1918.

In a cyclic process for the reduction of ores, etc., a part of the reducing gas is withdrawn for regeneration before it has traversed the entire column of ore and become spent,

and the remainder of the gas is burnt to preheat the ore. The gas is supplied to the reducing chamber 'd' from an electrically heated producer 's', and the greater part is withdrawn through opening 'k' and returned to the producer. If this gas is too hot to pass directly through the blower 'm' it is drawn through one of a pair of regenerators 'p', 'r' in which it is cooled, and forced through the other regenerator to be

heated again before entering the producer; valves 'o', 'q' enable the direction of flow to be reversed. The remainder of

the gas traverses the upper part 'c', 'b' of the ore column, air being used to heat the ore to consume any combustible constituent. Iron may be used as the heat-absorbing material in the regenerators.

Vulcanising Rubber. North British Rubber Company and B. D. Porritt, Fountainbridge, Edinburgh. British Patent, 129,798, of 1918.

The vulcanization of rubber by sulphur is accelerated by compounds resulting from the interaction of strong alkalis or strongly basic substances and monohydroxy derivatives of benzene or its analogues. Sodium phenate is one such compound in which the hydrogen of the hydroxyl group is replaced by the metal or equivalent radicle. In others, *m*- or *p*-cresol or β -naphthol may be the acidic group.

Sodium Permanganate. D. Tyrer, Stockton-on-Tees. British Patent, 130,844, of 1918.

Sodium permanganate is obtained from sodium manganate by first preparing barium manganate, then converting this into the permanganate, and finally decomposing the latter with a sodium salt. The conversion of the barium manganate into permanganate is effected by adding sulphuric acid very slowly, with or without the previous addition of a trace of barium permanganate. After treatment of the latter with a sodium salt, the product is evaporated until, on cooling, it solidifies to a crystalline mass of sodium permanganate.

Chemical Synthesis. L'Air Liquide Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude, Paris. British Patent, 130,068, of 1917.

Exothermic chemical syntheses, and particularly the synthesis of ammonia from its elements, are effected by the combined action on the constituents of the synthesis of a catalytic agent, a high temperature, and hyper-pressures, which are defined as pressures exceeding 500 atmospheres

and which may exceed 2,000 atmospheres. Under these conditions, when the reaction is once started, the heat of the reaction is more than sufficient to maintain the catalyst at a suitable temperature—for example, 500-700° C. The apparatus described comprises compressors C¹, C², which take in the mixed constituent gases, already compressed to 100-200 atmospheres, and deliver them under hyper-pressure to a catalysing apparatus K. The apparatus K consists of a long thick weldless tube T of steel or suitable metal screwed in a fluid-tight manner—for example, by embedding the joint in copper, on to a metal plug A, to which is also attached a thick tube G surrounded by a water-cooled jacket E. The tube T contains an inner open-ended thin-walled tube T¹, filled

with catalyst at the right-hand end. The external surface of the tube T may be kept at a suitable temperature by an oil bath, or by a boiler containing water under pressure, in which case steam under pressure is obtained as a by-product. The hyper-compressed gases entering the tube T through the plug B first traverse the space between the tubes T, T¹, being thereby heated, and then pass through the catalyst and along the tube T¹ to the condenser G, where the liquid product, for example ammonia, collects in the trap F and is withdrawn through a valve R. The uncombined gases may be passed through a second and third apparatus of successively decreasing size.

Strontium Peroxide. J. B. Pierce, West Virginia, U.S.A. British Patent, 130,840, of 1918.

Strontium peroxide is prepared by treating strontium oxide with oxygen under pressure, pressures of 1,500-1,800 lb. per sq. in. being mentioned. The reaction is facilitated by heat, 400-500° C. being suitable.

Metallic Chlorides. W. Heap, Heaton Chapel; and E. Newbery, Manchester University. British Patent, 130,626, of 1918.

Aluminium, magnesium, cerium, and rare-earth chlorides are obtained in anhydrous form by heating an oxide, hydrate, hydrated chloride, or weak acid salt, such as carbonate or oxalate, with phosgene gas or with a mixture of carbon monoxide and chlorine. When using a mixture of carbon monoxide and chlorine, a catalyst such as animal charcoal may be employed to convert part of the mixture into phosgene. According to the Provisional Specification, the invention is applicable to the production of calcium, iron, and other chlorides.

Fungicides. R. Mond, Sevenoaks, Kent; and C. Heberlein, London. British Patent, 130,709, of 1918.

Fungicides for horticultural and like purposes or for destroying fungi in water reservoirs consist of copper sulphate together with about 93 per cent. of the chemical equivalent quantity of an alkali carbonate or bicarbonate. It is stated that, owing to the formation of basic compounds, no free copper sulphate is left in solution, and that the maximum proportion of the colloidal compound produced is in the form of hydrosol. Preferred proportions are 4lb. copper sulphate crystals to 4.25lb. soda crystals. Solutions may be prepared for immediate use or the mixture may be put up in the dry form to be mixed with water for use. Dry mixtures of copper sulphate crystals with sodium bicarbonate alone or with a mixture of carbonate (crystals or anhydrous) and bicarbonate are stated not to interact on storing. Lime may be added to the mixtures as a substitute for part of the alkali carbonate or an inert substance may be added. A protective colloid, such as glue, may also be added. Mixtures containing various proportions of alkali carbonate greater than the chemical equivalent are also referred to.

Lubricants. H. M. Wells, St. Anne's-on-Sea; and J. E. Southcombe, Birkenhead. British Patent, 130,377, of 1918.

Lubricating oils are prepared by adding to a hydrocarbon lubricating oil a minute amount—e.g., 1-2 per cent.—of a substance other than soap which lowers the interfacial tension between oil and water. Where it is desired to prevent the product from forming an emulsion with water, acids of lower molecular weight, such as butyric or other volatile fatty acids, cinnamic acid, or water-soluble naphthenic acids, are added to the mineral lubricating oil. A product which is emulsifiable with water and suitable for marine-engine lubrication is obtained by the use of higher fatty acids such as those obtained from rape oil, wool grease, or whale oil. Oleine and other commercial fatty acids are preferably employed, the products so obtained being very similar to those obtained by compounding the corresponding animal and vegetable oils with mineral oils. The hydrocarbon oil may be derived from petroleum, coal, coal-tar, shale, colophony, etc.; petroleum jelly also is used.

Electrolytic Deposition of Metals. Q. Marino, Hendon, London. British Patent, 130,446, of 1918.

An electrolyte for plating consists of a solution of a phosphate or pyrophosphate of the metal in caustic alkali, to which has been added ammonium tartrate, salicylate, or citrate, or two or more of these salts. An alkali carbonate may replace part of the caustic alkali. Copper phosphate or pyrophosphate may be precipitated from a solution of the acetate, sulphate, or other salt, and washed in cold water before dissolving in alkali. The electrolyte may be heated, especially when plating hollow-ware. Copper anodes are readily dissolved. After thinly coating with this electrolyte, iron or steel may be more thickly plated in an ordinary electrolyte, such as copper sulphate solution. Alloys such as brass may be deposited.

Picric Acid. L. B. Holliday and A. Clayton, Deighton Chemical Works, Huddersfield. British Patent, 130,382, of 1918.

Picric acid is prepared by treating sulphonated phenol with a mixture of strong nitric acid and strong sulphuric acid; the mixed acid is added in two portions, the first (say, one-fourth of the whole) at or below 45° C., and after stirring for about an hour the remainder, heated to or above 70° C., is added, and the mixture heated to complete the reaction.

Organic Phosphorus Compounds. O. Imray, London. (A communication from the Society of Chemical Industry in Basle; Basle, Switzerland.) British Patent, 130,456, of 1918.

The pure sodium salt of the organic phosphorus reserve compound of green plants is prepared by dissolving the impure acid or salts thereof in dilute mineral acid, adding a solution of a ferric salt, treating the washed precipitate with excess of caustic soda solution, filtering, adding alcohol to the filtrate and crystallising, and finally recrystallising from water. The crystalline salt is formulated as $C_6H_5O_2P_6Na_{12} + 47 H_2O$ and the anhydrous salt as $C_6H_5O_2P_6Na_{12}$. Salts of calcium, barium, strontium, magnesium, copper, lead, manganese, iron, etc., may be obtained therefrom by double decomposition, and from these the free acid can be prepared; other salts are obtained by wholly or partially neutralising the free acid by inorganic or organic bases.

Organic Acid Anhydrides and Chlorides. A. Boake, Roberts and Co., Stratford, London; and T. H. Durrans, Oxford. British Patent, 130,399, of 1918.

Organic acid anhydrides or chlorides are prepared by the reaction of sulphur dioxide and chlorine upon anhydrous alkali or alkaline-earth salts of the acids in the presence of small quantities of the following bodies: esters of alcohols or phenols with organic or inorganic acids, ethers, aldehydes, acetals, phenols, or hydrocarbons; ethyl acetate, isoamyl formate, ethylphenyl acetate, methyl cinnamate, triphenyl phosphate, tricresyl phosphate, ethyl malonate, isobutyl chloride, benzyl benzoate, dibenzyl ether, eucalyptol, pinene, limonene, cinnamic aldehyde, anisic aldehyde, cresols, methylal, and isoamylacetal are specified as suitable. An example is given of the preparation of acetic anhydride; acetyl chloride, benzoyl chloride, butyric anhydride, and phenylacetic anhydride are also specified as products.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Lithopone. P. Desachy, Paris. British Patent, 126,628, of 1917. Convention date, October 19, 1917.

A process for the manufacture of a pigment comprising the sulphate of a metal of the alkaline earths and zinc sulphide utilises the process described in Specification 126,625 of producing zinc sulphide alone by causing a hot solution of sodium sulphide to react on an insoluble zinc product such as the oxide, carbonate, sulphite, etc. In preparing a mixture of barium sulphate and zinc sulphide, for instance, a mixed precipitate of barium sulphate and hydrated oxide, carbonate, or sulphite of zinc is first produced by treating a zinc sulphate solution with barium hydroxide, carbonate, or sulphite. The oxide or insoluble salt of zinc in the mixed precipitate is then converted into zinc sulphide by adding a hot solution of sodium sulphide or barium sulphide. The resulting mixture of barium sulphate and zinc sulphide is finally filtered, washed, calcined in a closed vessel with a small quantity of sulphur, and allowed to cool, with the exclusion of air.

Artificial Resins. Resan Kunsthaz-Erzeugungsges., Vienna. British Patent, 130,608. Convention date, March 22, 1918.

Artificial resins and intermediate condensation products are obtained by electrolysis mixtures of phenol, cresol, xylenol, or their derivatives with aldehydes or substances producing them, such as sodium acetate or methyl alcohol. Phenol, formaldehyde, and acetic acid rapidly give a hard but easily removable resin at the anode. A diaphragm may be used, the mixture being placed in the anode compartment, while the cathode compartment contains an electrolyte; this may be a condensing agent, such as sodium chloride, which is carried by the current into the anode compartment. The progress of the reaction may be followed by means of electric measuring instruments, and may be arrested at any desired stage. It may be regulated by varying the concentration, current, temperature, or pressure, or by stirring or circulating the electrolyte.

Nitrocellulose. J. Duclaux, Paris. British Patent, 130,619. Convention date, August 25, 1918.

Nitrocellulose is purified, and recovered from substances containing it, such as old or damaged powders, waste celluloid, etc., by forming a solution, for example, in acetone, methyl alcohol, alcohol-ether, methyl formate or acetate, or

ethyl formate, and either purifying the solution by dialysis or precipitating the nitrocellulose by addition of liquids which retain the impurities. The solution may be dialysed through membranes of viscose or of cellulose precipitated from cuprammoniacal solution, or of denitrated nitrocellulose, under a pressure equal to or greater than the osmotic pressure. The impurities pass through the membrane. In purifying by precipitation, the nitrocellulose may be precipitated by addition of water which may contain sulphuric acid or sodium carbonate, or by addition of organic liquids such as benzene, toluene, xylene, carbon tetrachloride, chloroform, or other chlorinated hydrocarbons. A quantity of benzene or other organic liquid insufficient to produce precipitation may be added to the nitrocellulose solution, which is then precipitated by addition of water. The precipitate may be washed and boiled with water, the vapours being condensed to recover the volatile solvents.

Hydrogen. L'Air Liquide Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude, Paris. British Patent, 130,358. Convention date, August 9, 1917.

Hydrogen is extracted from gas mixtures that contain it, for example, from water gas, coal gas, or coke-oven gas, by treating the gas mixture with ether at a pressure of 50 to 300 atmospheres, and at a temperature of -40 to -60° C., to dissolve out the other constituents. Other solvents, for example methyl acetate, which have the same power of dissolving carbon monoxide, the same rates of CO solubility, and the same temperature coefficient of this solubility ratio, may be employed. A suitable apparatus comprises a compressor C for the gas mixture, a refrigerating tank B, a thermally insulated absorption column A filled with balls or plates, a circulating pump E, and a tank D in which the solvent gives up its dissolved gases. The cooled and compressed gas, rising in the column A, meets the descending solvent, and practically pure hydrogen is liberated through the valve V. The saturated solvent escapes through the valve V² to the refrigerating tank B, and, before passing to the tank D, acts upon the piston E to assist in returning the unsaturated solvent, sucked up from the tank D, to the

top of the column A. To avoid loss of solvent, the dissolved gases may be liberated in two or more stages, first at a pressure greater than atmospheric, for example at 10 to 50 atmospheres, and finally at atmospheric or less than atmospheric pressure.

REPORTS OF COMPANIES.

American Smelting and Refining Company.

Earnings for 1918, after providing for fixed charges, were \$14,137,167., a decrease of \$10,898,770. on the previous year. Deducting the annual charge for depreciation of \$3,918,509., ore depletion \$1,521,121., appropriation for safety and welfare \$250,000., miscellaneous profit-and-loss charges \$740,038., there is left \$7,707,498. Preferred stock dividends amounted to \$4,247,773. For the first three quarters dividends were paid on the common stock at the rate of 6 per cent. per annum, and for the last quarter at the rate of 4 per cent. per annum, leaving at credit of profit-and-loss \$104,834.

DIVIDENDS.

ASBESTOS CORPORATION OF CANADA.—For the quarter ended September 30, a dividend of $1\frac{1}{4}\%$ on the common shares.

RIO TINTO COPPER COMPANY, LTD.—Interim dividend of 20s. per share on the ordinary (20 per cent.), against 30s. per share a year ago.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

British India.

H.M. Trade Commissioner at Calcutta reports that a Calcutta merchant wishes to get into touch with United Kingdom manufacturers of soaps and chemicals. (Reference No. 733.)

Canada.

The following inquiries have been received at the Canadian Government Trade Commissioner's Office, Portland House, 73, Basinghall Street, London, E.C. :—

A Montreal company would like to get into touch with United Kingdom importers of natural oxides and ochres.

A Montreal firm of importers and exporters have for sale a large quantity of sulphur, sulphuric acid, zinc oxide, and soda ash.

Hong Kong.

A firm of general import and export merchants at Hong Kong wish to get into touch with United Kingdom manufacturers of the following products: Sulphate of ammonia for fertilising purposes, dyes, and drugs and industrial chemicals. (Reference No. 744.)

A Hong Kong firm wish to get into touch with British importers of South China produce, especially cassia oil, peanut oil, aniseed oil, camphor oil, tea oil and lard. (Reference No. 745.)

Austria.

A firm of agents in Trieste desire to obtain agencies for United Kingdom manufacturers and firms dealing in soap and candles and copper compounds, who would buy on their own account. (Reference No. 746.)

Belgium.

A business man at Fléron, near Liège, is desirous of securing an agency for United Kingdom firms exporting chemical fertilisers. (Reference No. 748.)

Czecho-Slovakia.

Two merchants of good standing wish to act as agents for United Kingdom firms dealing in material for tanning leather, such as valonia, quebracho extract, mimosa tannin, and myrabolans; and phosphates and other materials for manures. (Reference No. 755.)

Italy.

H.M. Consul at Leghorn reports that a firm of agents in Leghorn desire to purchase soap on their own account. (Reference No. 761.)

An agent in Milan desires to obtain agencies for United Kingdom manufacturers of chemicals for the whole of Italy. (Reference No. 721.)

The following inquiry has been received at the British Chamber of Commerce for Italy, via Silvio Pellico 12, Milan:—

An agent in Milan wishes to obtain agencies, on a commission basis, for United Kingdom manufacturers and exporters of oils and fats for commercial purposes. (Reference No. 185.)

France.

A firm of exports agents in Paris, with extensive organisations (London office), desire to obtain exclusive agencies for United Kingdom manufacturers of tanning products, chemicals, including boric, citric, carbonic, and sulphuric acids, permanganate of potash, sulphate of copper, for France, Belgium, and Roumania, where they have offices and representatives. (Reference No. 710.)

The Acting British Consul at Nantes reports that an agent in Nantes desires to obtain agencies for United Kingdom manufacturers of paints, varnishes, and linseed oil, for Nantes and the West of France. (Reference No. 715.)

Spain.

A firm in Malaga desires to be put in touch with United Kingdom houses dealing with chemical products, such as oxalic acid, tripoli, bismuth, lac, ammonia, etc. (Reference No. 728.)

"BURGUNDY MIXTURE."—The short account of the work of Messrs. Robert L. Mond and C. Heberlein, on the chemistry of "Burgundy Mixture," which appeared in our last issue, was abstracted from *Nature*. Owing to an unfortunate oversight, the name of our contemporary was omitted.

JAMAICA DYEWOOD FACTORY.—According to the *Times Trade Supplement*, the Yorkshire Dyeware and Chemical Company have nearly completed an extensive factory at the south-western end of Jamaica. The factory buildings are situated on a site of 27 acres, the buildings alone covering six acres. Extensive machinery is being installed, and it is hoped that the factory will be in operation by the end of the year. A plentiful supply of water has been provided by means of a canal three miles in length. Large stocks of logwood and roots are being collected at the factory. To facilitate the purchase and transport of dyewoods, the company owns its own schooners. The undertaking will provide steady employment for a large number of hands.

SUGAR SHORTAGE.—The British Sugar Beet Growers' Society, Ltd., 14, Victoria Street, Westminster, S.W. 1, state that in the coming factory season in Germany there will be about 50 fewer raw-sugar factories in operation than in 1913. The area under sugar beet is said to have declined by about 19.4 per cent., the weight and sugar content of the crops being also seriously below the average. In France the damage has been on a much larger scale. Before the war there were 250 factories turning out one million tons of sugar annually. Of this about three-quarters were consumed in France, the remaining quarter being exported. The invaders destroyed 150 factories, and to-day the production is less than 150,000 tons per annum. The world's supply has fallen greatly below the demand, and will apparently continue to fall. The society, therefore, point out that it is urgently necessary that England should produce, as well as consume, sugar, and no longer be, as she was before the war, wholly dependent upon imported supplies.

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London, 90%, 2s. to 2s. 1d.; North, 1s. 10d. to 1s. 11d.; 50%, 1s. 10d. to 1s. 11d.; North, 1s. 9d. to 1s. 10d. naked. Carboic acid, crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 9d. to 9½d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch, 77s. 6d. to 80s.; East Coast, 70s. to 75s., f.o.b.; West Coast, 62s. 6d. to 65s., f.a.s. Solvent naphtha, naked, London, 90-190%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-160%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha, naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthalene, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 5¾d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid, 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b. other ports. Sulphate of ammonia: home trade, October £20. 10s., November £20. 15s., basis 24½%. Nitrate of soda, £22. to £22. 10s.

FERTILISER MATERIALS.

LIVERPOOL, THURSDAY.

Nitrate of soda is without alteration, the quotation on spot for 95-96% quality remaining at £20. per ton, net cash, f.o.r., Liverpool, prompt delivery. East Indian bone meal for shipment is without alteration, the quotation for October-December shipment being £17. 10s. per ton, net cash, ex ship, Liverpool, for 4½% ammonia and 52% phosphate quality. On spot, Liverpool, holders ask £16. per ton, net cash, ex store, for 4½% and 45% quality. Mineral Phosphates: No alteration is to be reported in this market, and values at present are only nominal. Dried blood continues scarce, the value being about 30s. per unit of ammonia per ton.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £103. 15s. to £104. cash; £103. 5s. to £103. 10s. three months; electrolytic, £113. to £120. Tin: Standard, £281. to £281. 5s. cash; £281. 15s. to £282. three months; Straits, £281.; English, £280. Lead: Soft foreign, £26. 15s.; English, £27. 15s. Spelter, £41. 10s.; hard, £28. to £30. Antimony, English regulus, 90%, £45. Aluminium £150. Nickel £205. delivered, packages extra. Quicksilver £19. 10s. Bismuth 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

There is a general feeling of relief at the settlement of the railway trouble, but deliveries of goods will be in arrears for some time owing to traffic congestion. Makers, on the whole, are well engaged with orders, and there is an active demand for all heavy chemicals. Home prices for caustic soda are unaltered on basis of £24. for 74%, but bleaching powder has been advanced to £17., packages extra. Bicarbonate of soda, 58% alkali, and soda crystals are higher at £8. 5s., £6. 10s., and £5. 10s. respectively, in bags. Saltcake has also been advanced to 70s. per ton, carriage paid. Chlorate of soda easy at 6d. per lb. Potash, 1s. per lb. Bichromates are unchanged at 1s. 6d. and 11d. for potash and soda respectively. Nitrite of soda scarce at £60. per ton. Sulphate of copper continues flat, and price only nominal at £40. per ton. Phosphate of soda steady at £26. Concentrated sodium sulphide, £24., and commercial hyposulphite,

£16. 10s., on rails. There is a little more arsenic offering, but price is firm at £60. per ton. Barium chloride easier at £23. per ton. Yellow prussiate of soda scarce and dearer at 10½d. per lb. Potash dull at 1s. 9d. per lb. Carbonate of potash 85% higher at £103. per ton. Lead salts are again quiet, but prices are maintained: English white acetate, at £83.; brown, £68.; nitrate, £56. per ton. Brown and grey acetate of lime unaltered at recent rates. Acetate of soda lower at £50. per ton. Prices for acetic acid are steady. Oxalic acid, foreign make, is now selling at 1s. 1d. per lb., and price has a lower tendency. Copperas is moving off fairly well at £4. 5s., delivered in owner's wagons.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

The announcement made on Monday morning of the settlement of the railway workers' strike changed the buying and selling conditions in the market for the better. Feelings of apprehension and uncertainty, which had induced restraint in the market, passed away and left a feeling of freedom under which buyers were more disposed to place orders for fresh supplies of chemicals, especially for deliveries at forward dates. More inquiries on export account have come to hand, so that a very fair degree of activity has prevailed in the market. Bleaching powder has been in somewhat freer request. Prices are £17. per ton, on rail or conveyance in buyers' packages, and £15. to £18. per ton, for export. Chloride of calcium continues quiet, and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has been well inquired for, and is £24. per ton for 76%, £22. per ton for 70 to 72%, and £19. per ton for 60 to 62%. Nitrate of soda has been more in demand, and is £21. to £22. per ton. Saltcake has been quieter, and is £6. 10s. per ton, in casks, f.o.b. Soda crystals have sold freely, and are £5. 10s. per ton in 2cwt. bags, f.o.r. at works. Bicarbonate of soda has been in good request, and is £8. 5s. to £10. per ton, according to terms of delivery. Borax has been steadily called for, and is still in light supply. Ordinary is £45. per ton; and powdered, £46. per ton, in bags. Ammonia alkali has sold readily, and is £6. 10s. per ton f.o.r. at works. Hyposulphite has been in moderate demand, and is £16. per ton for ordinary, and £21. per ton for pea crystals, in 1cwt. kegs. Sulphite of sodium has had a limited sale, and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals, in 1cwt. kegs. Bichromate of soda has been rather more in request, and is 9d. per lb. Phosphate of soda has been in moderate demand, and is £25. per ton. Sulphide of sodium has been quiet, and is £20. per ton in casks, and £22. per ton in drums. Chlorate of potash has been but little called for, and is 1s. to 1s. 2d. per lb. Permanganate of potash has been rather more in request, and is 3s. 3d. per lb. Sulphate of potash has been quiet, and is £30. per ton. Carbonate of potash has again been in very fair inquiry, and in limited supply. It is £95. per ton for 80 to 85%. Caustic potash has been in fairly active demand, and is £120. per ton. Nitrate of potash has sold rather freely, and is £55. to £60. per ton for refined, and £40. per ton for ordinary. Canadian potashes have been very quiet. First quality Montreal, are £200. to £220. per ton, and second quality, £190. to £210. per ton. Bichromate of potash has been in quietly steady demand, and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been more inquired for, and is 1s. 9d. to 1s. 10d. per lb. Sal ammoniac has sold more readily. Lump is £90. per ton; seconds, £80.

per ton; and ground, £5. per ton extra. Sulphate of ammonia has been in moderate request, and is £20. 10s. per ton for October; £20. 15s. for November, £21. for December, £21. 7s. 6d. for January, 1920, £21. 15s. for February, and £22. per ton for March to May, 1920. Carbonate of ammonia has been rather more in request, and is 6½d. per lb. Muriate has had a very limited sale, and is £50. to £55. per ton, according to quality. Magnesia has sold somewhat readily. Carbonate is £2. 5s. per cwt., and sulphate, £10. to £16. per ton, according to grade. Alum has been well inquired for, and the supply at hand has been small. Quotations are: £18. 10s. per ton for the home trade, and £18. 10s. to £19. 10s. for export. Aluminoferric has been in moderate inquiry, and is £8. 10s. to £12. per ton, according to quality. Sulphate of alumina has been rather more in request, and is £12. to £17. per ton according to grade. Sulphur has been in good request. English flowers are £32. per ton, and are still scarce. Roll is £28. per ton, and rock, £22. per ton, in bags, f.o.r. Sicilian grades are: flowers, £28. per ton; roll, £22. 10s. per ton, and rock, £17. 15s. per ton. Cream of tartar has had a moderate sale, and is £11. 15s. to £12. per cwt. Tartaric acid has been in quietly steady demand, and is 3s. 1d. to 3s. 2d. per lb. Boracic acid has been in very fair request, and is £72. per ton for crystals, and £74. per ton for powdered. Oxalic acid has sold a little more freely, and is 1s. 2d. to 1s. 3d. per lb. according to requirements for delivery. Citric acid has been in very fair demand, and is 4s. 4d. per lb. White acetate of lead has been very quiet, and is £85. per ton. Arsenic has been more in request. White powdered continues firm in price, and is £60. per ton. Sulphate of copper continues very quiet. Prices are £41. to £42. per ton for home trade uses, and £42. to £43. per ton for export.

TYNE CHEMICAL REPORT.

TUESDAY.

Business in chemicals has been considerably interfered with on account of the railway strike—not only for home consumption, but also for export. Steamers are being held up on account of coal restriction order. Trade is plentiful and now the strike is at an end, business is being quickly resumed.

Prices per ton net are nominally:—Bleaching powder, softs, £17.; caustic soda, 74/77% £23. 5s., do. 70% £22., do. 60% £20.; recovered sulphur, 2cwt. bags £23.; hyposulphite of soda 5/7cwt. casks £19., 1cwt. kegs £25.; sulphite of soda, 5/7cwt. casks £12., do. 1cwt. kegs, £20.; silicate of soda, 75° Tw. £9. 12s. 6d.; do. 100° Tw. £10., do. 140° Tw. £10. 10s.; soda crystals, 2cwt. bags, £5. 10s.; sulphate of soda (salt cake) in bulk £4.; pure white sulphate of alumina £19. 10s.; blanc fixe £22.; sulphide of sodium, crystals, £18., do. refined concentrated solid, 60/62%, £25.; hydrate of barium, crystals, £56.

COALS.—Market is very steady, but with the export restrictions still operative for France and neutrals, actual business is

difficult. Prospects for a firm market are well assured for some time ahead. Quotations:—Best Northumbrian steam 100s. per ton, seconds 95s. to 100s.; Northumbrian small coals 75s. to 80s., seconds 70s. to 75s.; best Durham gas coals 80s. to 85s., seconds 65s. to 75s.; Durham bunkers 70s. to 80s., seconds 60s. to 70s.; foundry coke 100s.; gas coke 95s. to 100s.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Wednesday.

Considerable gratification was felt at the beginning of the week when it became known that the railway strike had terminated, and since then an effort has been made in the Glasgow and West of Scotland chemical trade—as in other industries—to get things on a normal footing again. Deliveries, however, are still uncertain owing to the transit problems, which are still in evidence, and the general market conditions are inclined to be quiet. There are some price variations occurring here and there, and the following list indicates the latest quotations: Arsenic, £62. per ton, net, Glasgow; bicarbonate of soda, £9. 15s. and £10. 10s. per ton for 6-8 casks and 1cwt. kegs, net, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags, and borax crystals £39. for 2cwt. bags, carriage paid; caustic soda, white, 70-72%, £24. per ton, net, Glasgow; chlorate of potash, 1s 1d. per lb., net, Glasgow; chlorate of soda, 8d. per lb., net, Glasgow; citric acid, 4s. 4d. per lb., 5%, Glasgow; cream of tartar, 98%, £11. 10s. per cwt., net, Glasgow; paraffin wax U.K. deliveries 125°, 6½d. to 6½d.; 121-30°, 5½d. to 5½d.; 118-200°, 5d.; 110-120°, 4d. to 4½d.; and 98-102°, 4d. to 4½d.; salammuniac, £80. and £75. per ton, net, any port, for first and second lump respectively; salammuniac crystals, £85. per ton, net, Glasgow; saltpetre, £3. 4s. net, Glasgow; tartaric acid, 3s. 3d. per lb., 5% Glasgow.

As far as the different sea oils are concerned, business is also keeping to the quiet side, but during the week a number of fairly important deals are stated to have been carried through here and there. Among the whale oils the yellow variety is still unobtainable: while brown and black are keeping steady at their old quotations of 76s. and 74s. respectively. Pale, on the other hand, however, continues on a lowering tendency, and the latest price is 95s., as against 102s. about a month ago. Newfoundland cod is steadily maintained at 80s., and pale seal continues to change hands at 96s.; but Menhaden is easier in quotation at 83s., as against the previously quoted 86s.

Naturally, the Glasgow and West of Scotland coal trade was acutely effected by the railway strike, and at the moment of writing matters at the pithead are far from normal or easy. There is, however, a noticeable improvement in the general position, and the accumulation of output is gradually being lessened with more transport available.

Adelaide, 119 pkgs.; Barcelona, 20 drms.; Batoum, 120 drms.; Bilbao, 200 drms.; Calcutta, 11 drms.; Constantinople, 429 drms.; Coronel, 75 drms.; Copenhagen, 518 drms.; Karachi, 780 drms.; Las Palmas, 5 drms.; Kobe, 740 drms.; Manila, 100 drms.; Melbourne, 163 drms.; 250 cs.; Naples, 66 drms.; Osaka, 290 drms.; Pernambuco, 80 drms.; Piraeus, 800 drms.; South Georgia, 14 drms.; Smyrna, 773 drms.; Stockholm, 5 cks.; Volo, 135 drms.; Yokohama, 746 drms.

CHEMICALS (otherwise undescribed)

Antwerp, 1 t., £39.; Copenhagen, 20 t., £1,495.; Kampen, 2 t. 2 c., £153.

CHINA CLAY—

Bombay, 283 t.; Calcutta, 60 cks.

CITRIC ACID—

Rotterdam, 1 c., £25.

COAL PRODUCTS (otherwise undescribed)

Antwerp, 1 t. 5 c., £420.; Conakry, 500 gals., £33.; Halifax, N.S., 3 t., £1,256.; Shanghai, 7 t. 1 c., £3,362.

COAL PRODUCTS—

Benzole

Algiers, 11 t. 4 c., £250.

Carbolacene

Oporto, 2 t. 18 c., £75.

Carbolic Acid

Karachi, 2 c., £12.; Kobe, 28 t. 14 c., £1,700.; Lagos, 2 c., £3.; Rio de Janeiro, 2 t. 19 c., £112.

Creolina

P. Calabro, 1 t. 11 c., £116.

Creolite

Valencia, 3 t. 18 c., £248.

Creosote

Barcelona, 1 t. 1 c., £10.; Christiania, 14,400 gals., £612.

Naphthalene

Accra, 1 c., £5.; Aden, 21 t., £389.; Coomassie, 1 c., £5.; Guatemala, 2 c., £15.; Mombasa, 10 t. 3 c., £195.

Pitch

Axim, 18 c., £5.; Sierra Leone, 1 t. 2 c., £6.

Tar

Accra, 1 t. 4 c., £8.; Cape Coast, 1 t. 6 c., £13.; Grand Bassa, 1 t. 1 c., £9.; Monrovia, 1 t. 1 c., £9.; Sherbro, 2 t. 13 c., £89.

COPPER SULPHATE—

Barcelona, 5 t. 5 c., £200.; Calcutta, 2 t. 18 c., £118.; Karachi, 1 t. 10 c., £61.; Piraeus, 3 t., £118.; Salonika, 19 c., £40.; Volo, 10 t., £394.

COPPERAS—

Salonika, 45 pkgs.

CREAM OF TARTAR—

Tammerfors, 10 c., £120.; Talcahuano, 1 c., £51.; Valparaiso, 2 c., £103.

DISINFECTANTS (otherwise undescribed)

Calabar, 1 c., £3.; Calcutta, 4 t. 9 c., £196.; Coomassie, 9 c., £35.; Colombo, 1 t. 17 c., £52.; Dakar, 9 c., £23.; Ferrol, 2 qrs., £1.; Havana, 2 t. 16 c., £124.; Hong Kong, 16 c., £34.; Karachi, 2 t. 16 c., £74.; Lagos, 2 c., £6.;

DISINFECTANTS (otherwise undescribed)

Lisbon, 2 c., £12.; Pt. Said, 10 c., £30.; Pernambuco, 4 c., £57.; Rangoon, 3 c., £42.; Sierra Leone, 1 c., £9.; Sapele, 5 c., £10.; Secondee, 11 c., £51.; St. John's, 2 t. 8 c., £380.

DYESTUFFS—

Aniline Dye

Antwerp, 17 t. 7 c., £930.; Barcelona, 19 t. 15 c., £4,813.; Boston, 13 t. 14 c., £6,047.; Calcutta, 1 t. 9 c., £863.; Colombo, 2 c., £98.; Havre, 7 c., £90.; Lisbon, 1 t. 5 c., £229.; Madras, 5 t. 18 c., £1,627.; Mollendo, 1 c., £166.; Montreal, 1 t. 10 c., £320.; New York, 4 t.; 1 c., £1,763.; Piraeus, 10 c., £66.; Rouen, 12 c., £240.

FERRO TUNGSTEN—

Rio de Janeiro, 5 t.; Rotterdam, 5 t.

FORMALINE—

Belgrade, 3 c., £11.

GLUE—

Kobe, 20 bgs.

GLUE, SIZE, AND GELATINE—

Bombay, 3 pkgs.; Boston, 101 pkgs.; Rotterdam, 10 pkgs.; Sydney, 80 tins.

GLYCERINE (DISTILLED)—

Hong Kong, 100 cs.; Kobe, 32 drms.

IRON OXIDE—

La Guaira, 6 cks.

IRON SULPHATE—

Amsterdam, 3 t., £30.; Guatemala, 2 c., £12.

LEAD ACETATE—

Piraeus, 2 c., £9.

LEAD CARBONATE—

Guatemala, 1 c., £8.

LEAD NITRATE—

Antwerp, 6 c., £16.; Rouen, 19 c., £60.

MAGNESIUM CHLORIDE—

Bombay, 45 t. 1 c., £370.; Rangoon, 1 t., £18.

MAGNESIUM OXIDE—

Barcelona, 5 c., £10.

MAGNESIUM SULPHATE—

Colon, 7 c., £15.

MERCURY PERCHLORIDE—

Belgrade, 2 qrs., £20.

NICKEL AND AMMONIUM SULPHATE—

Buenos Ayres, 10 c., £30.

NICKEL SALTS—

Barcelona, 1 t. 10 c., £79.

NICKEL SULPHATE—

Barcelona, 17 c., £245.

OXALIC ACID—

Lisbon, 10 c., £56.

PARAFFIN WAX—

Fiume, 400 bgs.

PHOSPHORUS—

Shanghai, 100 cs.

PHOSPHORUS (AMORPHOUS)—

Cape Town, 13 c., £180.; Paranagua, 1 t. 12 c., £429.

PITCH—

Aviles, 275 t., £1,500.; Bilbao, 9 t. 5 c., £230.; Lagos, 3 t. 5 c., £18.; Lisbon, 3 c., £14.; Monrovia, 5 c., £4.

POTASSIUM BICARBONATE—

Antwerp, 18 c., £145.; Allegro, 5 c., £40.; Copenhagen, 5 t. 6 c., £342.; Lisbon, 15 c., £80.; Piraeus, 8 c., £62.

POTASSIUM CHLORATE—

Funchal, 1 c., £7.; Patras, 6 c., £39.

POTASSIUM IODIDE—

Calabar, 1 c., £142.

POTASSIUM NITRATE—

Malta, 6 c., £18.

POTASSIUM PRUSSATE—

Lisbon, 5 c., £45.

POTASSIUM SULPHATE—

Teneriffe, 1 t., £41.

RED LEAD—

Antwerp, 38 cks.

ROSIN—

Rio de Janeiro, 6 pkgs.

SALAMMONIAC—

Bombay, 7 t. 7 c., £493.; Durban, 2 c., £7.; Famagusta, 2 c., £7.; Galatz, 10 c., £36.; Karachi, 6 t., £434.; New York, 2 t., £160.; Palermo, 1 t., £72.; Piraeus, 1 t. 9 c., £102.; Philadelphia, 2 t., £148.; Rangoon, 1 t. 1 c., £73.; Salonika, 3 t. 2 c., £219.

SALT—

Bombay, 8 t.; Boston, 350 t.; Buenos Ayres, 127 t.; New York, 150 t.; Rangoon, 1,654 t.; Stavanger, 100 t.; Stockholm, 350 t.; Transvaal, 170 t.

SALTCAKE—

Sao Paulo, 11 t. 2 c., £50.

SALTPETRE—

Pernambuco, 5 t. 17 c., £359.

SHEEP DIP—

Panama, 4 c., £9.; Pt. Elizabeth, 17 t. 2 c., £664.

SOAP—

Aden, 50 cs.; Algiers, 1,440 bxs., 250 cs.; Amsterdam, 350 bxs.; Antofagasta, 100 cs.; Antwerp, 3,200 bxs., 1,210 cs.; Bangalore, 15 pkgs.; Bangkok, 245 pkgs.; Barcelona, 250 bxs.; Bengali, 107 pkgs.; Bluefields, 5 pkgs.; Bombay, 2,235 bxs.; Braila, 771 cs.; Calcutta, 21 bxs.; Calicut, 26 cs.; Callao, 350 cs.; Casablanca, 51 cs.; Cochich, 8 cs.; Constantinople, 16 kgs., 1,800 cs., 150 bxs.; Copenhagen, 5 cs., £268.; Dambi, 100 bxs.; Dongalla, 50 bxs.; Dunkirk, 50 kgs., 6,965 cs.; Durban, 250 cs.; Genoa, 500 cs., 200 bxs.; Gibraltar, 50 kgs., 610 cs., 515 bxs.; Gothenburg, 6 brls., 126 cs.; Havana, 25 cs.; Hong Kong, 1,000 bxs.; Iquitos, 760 bxs.; Kano, 1 cs.; Karachi, 198 cs.; Kingston, 1,063 cs.; Lagos, 2 bxs.; Larache, 100 bxs.; Las Palmas, 720 bxs.; Leghorn, 500 bxs.; Malta, 123 cs.; Manao, 150 bxs.; Melilla, 100 bxs.; Mombasa, 1,000 cs.; Piraeus, 10 bxs.; Port-au-Prince, 25 bxs.; Punta Arenas, 36 bxs.; Pt. Stanley, 30 bxs.; Pt. Sudan, 1,405 bxs.; Quebec, 20 bxs.; Rabat, 1,135 bxs.; Rotterdam, 1,620 bxs.; South Georgia, 20 pkgs.; Tampico, 2 pkgs.; Teneriffe, 709 bxs.; Trebizond, 6 cs.; Trinidad, 2,250 bxs.; Tripoli, 155 cs.; Truxillo, 50 bxs.; Valletta, 70 pkgs.; Tuticorin, 43 cs.; Varna, 10 cs.; Vera Cruz, 10 bxs.; Volo, 40 cs.

SODA ASH—

Calcutta, 939 pkgs.; Christiania, 100 bgs.; Copenhagen, 492 bgs.; Freemantle, 42 cks.; Hong Kong, 1,680 bgs.; Melbourne, 1,000 bgs.; Karachi, 1,100 bgs.; Mitylene, 100 bgs.; Montreal, 200 cks.; Oporto, 100 bgs.; Monte Video, 430 cks.; Piraeus, 280 brls.; Rotterdam, 100 brls.; Salonika, 300 brls.; Singapore, 63 brls.; Smyrna, 505 brls.; Sydney, 543 brls.; Syra, 160 brls.; Trondhjem, 250 bgs.; Venice, 200 bgs.; Yokohama, 930 brls.

Karachi, 50 bgs.; Pernambuco, 10 pkgs.; Piraeus, 100 pkgs.; Salonika, 34 pkgs.; South Georgia, 25 brls.; Trieste, 305 brls.; Tangiers, 15 brls.

SODIUM AND POTASSIUM TARTRATE—

Oporto, 2 c., £20.

SODIUM BICARBONATE—

Braila, 500 brls.; Callao, 27 cks.; Christiania, 100 bgs.; Genoa, 129 pkgs.; Karachi, 640 pkgs.; Las Palmas, 7 pkgs.; Leghorn, 450 pkgs.; Lisbon, 20 pkgs.; Montreal, 2,000 bgs.; Monte Video, 50 cks.; Oporto, 50 kgs.; Piraeus, 60 pkgs.; St. Vincent, 20 pkgs.; Pt. Sudan, 20 pkgs.; Valencia, 4 pkgs.

SODIUM BICARBONATE—

Valparaiso, 1,066 pkgs.
Yokohama, 300 pkgs.

SODIUM CYANIDE—

Cape Grace, 100 cs.; Corinto,
232 cs.; La Union, 50 cs.

SODIUM HYPOSULPHATE—

Stamboul, 4 pkgs.

SODIUM SILICATE—

Catania, 61 cks.; Monte Video,
160 brls.; Oporto, 39 brls.;
Pernambuco, 32 pkgs.; Vladivostock,
75 cks.

SODIUM SULPHIDE—

Algiers, 33 cks.

STEARINE—

Aarhus, 57 brls.

SULPHUR—

Barcelona, 1 t. 1 c., £69.;
Panama, 1 c., £8.

SULPHUR (FLOWERS)—

Benguella, 1 c., £2.; Nantes,
13 t., £315.

SULPHURIC ACID—

Mombasa, 4 c., £12.; Pt. Sudan,
3 c., £13.; Singapore, 3 qrs., £2.

TALLOW—

Marseilles, 139 brls.

TANNIC ACID—

Barcelona, 7 c., £160.

TAR (WOOD)—

Colombo, 1 t., £8.; Malacca,
3 t. 16 c., £25.

TARTARIC ACID—

Jesseltown, N.B., 1 c., £18.;
Madras, 2 t., £621.; New York,
5 t., £1,543.; Rotterdam, 22 lb.,
£8.

TURPENTINE—

Copenhagen, 51 brls.

WAX—

Bucharest, 10 bgs.

WOOD ACID—

Colombo, 19 c., £6.

WOOD PRESERVATIVE—

Bilbao, 3 t. 15 c., £85.; Funchal,
1 c., £5.

ZINC CHLORIDE—

Rangoon, 5 t. 4 c., £260.

ZINC OXIDE—

Barcelona, 7 c., £29.

LONDON.

Week ending October 1.

ACETIC ACID—

Genoa, 63 cks., £974.; Leghorn,
2 crbys., £13.; Melbourne, 2 cs.,
£26.; Rotterdam, 18 cks., £189.;
Salonika (F.), 30 crbys., £225.;
Valparaiso, 1 c., £13.; Well-
lington, 6 cs., £19.

ACETO SALICYLIC ACID—

Fremantle, 1 cs., £21.; Genoa,
2 cs., £17.; Melbourne, 6 pkgs.,
6 cs., £299.; Treport, 1 kg., £27.

ALUM—

Batavia, 10 cks., £65.; Brussels,

Elizbeth, 5 cs., £10.; Samarang,
1 cs. (pt.), £6.; Singapore, 2 cs.,
£7.; Suva, 4 cs., £8.; Italy,
via Treport, 16 cs., £32.

AMMONIUM BENZOATE—

Punta Arenas, 1 cs. (pt.), £7.

AMMONIUM BROMIDE—

Antwerp, 4 cs., £111.; Bombay,
3 cs. (pt.), £39.; Durban (F.),
1 cs., £16.

AMMONIUM CARBONATE—

Antwerp, 1 t., £40.; Auckland,
2 c., £9.; Bangkok, 9 c., £52.;
Buenos Ayres, 8 t. 9 c., £16.;
Callao, 10 c., £50.; Calcutta,
2 c., £8.

AMMONIUM CARBONATE—

Cape Town, 2 c., £8.; Rangoon,
2 t. 13 c., £215.; Talcahuano,
4 c., £15.

AMMONIUM CHLORIDE—

Pt. Said, 1 cs., £12.

AMMONIUM CITRATE—

Buenos Ayres, 4 cs. (pt.), £25.

AMMONIUM MURIATE—

Bombay, 5 t. 2 c., £369.; Con-
stantinople, 2 t., £157.; Mel-
bourne, 5 c., £19.; Tripoli, 5 c.,
£16.

AMMONIUM PERCHLORIDE—

Antwerp, 166 bxs., £215.

AMMONIUM PHOSPHATE—

Brussels, 1 kg., £14.

AMMONIUM SULPHATE—

Dunkirk, 150 t., £3,450.

AMMONIUM SULPHO CYANIDE—

Shanghai, 1 cs. (pt.), £5.

AMYL ACETATE—

Antwerp, 23 drms., £1,560.;
Rotterdam, 15 drms., £1,480.

AMYL NITRATE—

Buenos Ayres, 1 cs., £34.

ANTIMONY—

Rotterdam, 10 t.

ANTIMONY SULPHIDE—

Antwerp, 8 cks., £209.; Mon-
treuil, 16 cks., £549.; New York,
5 cks., £245.

ARSENIC—

Ghent, 36 drms., £27.

BARIUM HYDRATE—

Paris, 8 cks., £21.

BARIUM NITRATE—

Bombay, 15 kgs., 14 cks., £208.

BISMUTH CARBONATE—

Melbourne, 4 cs. (pt.), £177.

BISMUTH NITRATE—

Mauritius, 2 cs. (pt.), £14.

BISMUTH SUBNITRATE—

Copenhagen, 2 cs., £313.; Mel-
bourne, 4 cs. (pt.), £10.; Shan-
ghai, 1 cs., £11.

BISULPHITE—

Karachi, 5 t. 7 c., £128.

BITUMINOUS SOLUTION—

Hong Kong, 50 drms., £121.

BORAX—

Christchurch, 1 t., £40.; Colombo
5 c., £10.; Dunedin, 10 c., £20.;
Fremantle, 6 c., £12.; Rotter-
dam, 10 t., £390.; Wellington,
1 t., £40.

BORIC ACID—

Switzerland, via Antwerp, 9 t.
17 c. (F.), £709.; Beyrout, 5 c.,
£19.; Canton, 5 c., £20.; Dun-
edin, 10 c. (F.), £37.; Karachi,

Trinidad, 2 c., £5.

HYDROGEN PEROXIDE—

Singapore, 4 cs., £21.

HYPOPHOSPHORIC ACID—

Adelaide, 1 cs., £9.; Melbourne,
2 cs., £32.

IODINE (RESUBLIMED)—

Genoa, 20 cs., £1,800.; Mauritius,
3 cs. (pt.), £45.

IRON AND AMMONIUM CITRATE

Launceston, 1 cs. (pt.), £5.;
Melbourne, 4 cs. (pt.), £7.

IRON AND AMMONIUM OXALATE

Ghent, 1 cs., £22.

IRON PERCHLORIDE—

Calcutta, 1 cs., £10.

IRON PYROPHOSPHATE—

Montreal, 1 cs., £13.

KEISELGHUR—

Jamaica, 11 c., £13.

LACTIC ACID—

Brussels, 6 cks., £58.; Rosario,
2 cks. (pt.), £18.

LEAD AND MANGANESE

RESINATE—
New York, 2 brls., £18.; Stock-
holm, 30 cks., £380.

LEAD LINOLEATE—

Amsterdam, 4 brls., £159.; New
York, 2 brls., £52.

LEAD RESINATE—

New York, 2 brls., £45.

MAGNESIA (CALCINED)—

Guayaquil, 2 cs., £20.; Paris,
3 cks., £16.; Rouen, 2 cks., £8.

MAGNESIUM CARBONATE—

Beyrout, 1 ck., £9.; New York,
1 cs. (pt.), £20.

MAGNESIUM SULPHATE—

Bombay, 5 c., £

MANGANESE LINOLEATE—
New York, 2 brls., £47.

MANGANESE RESINATE—
Amsterdam, 1 ck., £17.

MERCURY OXIDE—
Mauritius, 3 cs. (pt.), £6.

MERCURY OXYDATE—
Copenhagen, 1 cs., £85.

MERCURY PERCHLORIDE—
Calcutta, 1 cs., £7.

METHYL SALICYLATE—
Sydney (F.), 1 cs. (pt.), £8.

MINERAL WAX—
Copenhagen, 10 c.

MIRBANE OIL—
Barcelona, 1 dr., £60.; Mont-
real, 1 dr., £55.

**NICKEL AND AMMONIUM
SULPHATE**—
Soerabaya, 2 kgs., £24.

NICKEL SALTS—
Paris, 48 cks., £50.

OXALIC ACID—
Durban, 1 cs., £10.

PARAFFIN WAX—
Antwerp, 11 c.; Liman, 20 t. 10 c.

PHOSPHORIC ACID—
East London, 4 cs., £6.; Lisbon,
9 crbys., £73.; Treport, 10 crbys.,
£86.

POTASSIUM ACETATE—
Fremantle, 2 cs. (pt.), £5.

POTASSIUM BICHRIMATE—
Adelaide, 1 cs., £10.; Boulogne,
3 cks., £240.; Jamaica, 1 cs.,
£50.

POTASSIUM BIOXALATE—
Fremantle (F.), 1 kg., £10.

POTASSIUM BROMIDE—
Bombay, 4 cs. (pt.), £32.;
Launceston (F.), 1 cs., £8.;
Mauritius, 3 cs. (pt.), £10.

POTASSIUM CHLORIDE—
Brussels, 4 c., £30.; Cyprus,
1 c., £10.

POTASSIUM CITRATE—
Bombay, 2 cs., 1 cs. (pt.), £48.

POTASSIUM CYANIDE—
Bombay, 2 c., £53.

POTASSIUM HYDROXIDE—
Beyrout, 1 cs. (pt.), £5.

POTASSIUM HYPO—
Montreal, 1 cs., £35.

POTASSIUM IODIDE—
Alexandria, 1 cs. (pt.), £5.;
Amsterdam, 1 cs., £168.; Bang-
kok, 5 cs., £500.; Durban, 1 cs.,
£46.; Genoa, 1 cs. (pt.), £52.;
Melbourne, 2 cs., £80.

POTASSIUM SULPHATE—
Brussels, 2 cs., £14.

**POTASSIUM SULPHOGUAIA-
COLATE**—
Buenos Ayres (F.), 4 cs. (pt.),
£60.

PYROGALLIC ACID—
Bombay, 1 cs. (pt.), £7.; Hong
Kong, 1 cs. (pt.), £8.; Soerabaya,
2 cs. (pt.), £22.

QUININE—
Calcutta, 27,096 ozs.

ROCHELLE SALTS—
Montreal, 8 cks., £222.

SALICYLIC ACID—
Aalborg, 4 brls., £52.; Copen-
hagen (F.), 2 brls., £26.; Shan-
ghai, 1 brl., £13.

SALT—
Lisbon, 2 t.; Lyttleton, 170 t.;
Madras, 2 t. 10 c.; Rangoon,
11 c.; Santiago, 5 c.

SALTPETRE—
Amsterdam, 5 t., £267.; Dur-
ban, 10 c., £31.; East London,
17 c., £59.; Genoa, 5 t., £250.;
Lisbon, 2 t. 4 c., £115.; New
York, 50 t. (F.), £1,929.; Oporto,
18 c., £45.; Pt. Elizabeth, 1 c.,
£15.

SHEEP DIP—
Buenos Ayres, 66 t. 4 c., £2,808.;
Cape Town, 2 t. 7 c., £95.;
Punta Arenas, 8 t. 6 c., £547.

SILVER NITRATE—
Mauritius, 2 cs. (pt.), £12.

SOAP—
Adelaide, 1 c.; Alexandria, 1 t.
15 c.; Amsterdam, 1 t. 3 c.;
Antwerp, 253 t.; Auckland,

1 c.; Yokohama, 6 c.

SODA ASH—
Rotterdam, 10 t., £73.

SODA CRYSTALS—
Tripoli, 1 t., £5.

SODIUM ACETATE—
Brussels, 3 cks., £30.

SODIUM ARSENATE—
Penang, 1 kgs., £22.

SODIUM ARSENITE—
Durban, 2 t. 1 c., £110.

SODIUM BICARBONATE—
Calcutta, 2 c., £7.; Durban, 16 c.,
£30.; Libau, 1 t., £14.; Monty-
luoto, 2 t., £26.; Shanghai,
10 c., £15.; Tripoli, 10 c., £5.;
Wasa, 3 t., £39.; Wellington,
2 c., £5.

SODIUM BROMIDE—
Bombay, 1 cs. (pt.), £7.; Dur-
ban (F.), 1 cs., £15.

SODIUM HYDROXIDE—
Madras, 1 cs. (pt.), £7.

SODIUM HYPOSULPHITE—
Amoy, 1 t., £27.

SODIUM IODIDE—
Genoa, 1 cs. (pt.), £14.; Rio de
Janeiro, 1 cs. (pt.), £5.

SODIUM METABISULPHITE—
Paris, 4 t. 18 c., £128.; Toronto,
2 t. 19 c., £70.

SODIUM NITRATE—
Bombay, 18 kgs., 17 cks., £343.

SODIUM PRUSSATE—
Kobe, 3 t., £215.; Philadelphia,
16 c., £70.

SODIUM SILICATE—
Durban, 1 t. 1 c., £46.

SODIUM STANNATE—
Paris, 1 ck., £97.

SODIUM SULPHATE—
Fremantle, 1 t., £13.; Samarang,
1 kg., £6.

SODIUM SULPHIDE—
Singapore, 1 t., £24.

SODIUM SULPHITE—
Brussels, 2 pkgs., £9.

SULPHUR—
Antwerp, 5 t., £150.; Jamaica
(F.), 6 c., £8.

SULPHUR (ROLL)—
Karachi, 10 c., £12.; Trinidad,
6 t. 10 c., £276.

SUPERPHOSPHATES—
Colombo, 50 t., £600.; Durban,
20 t., £210.

TALLOW—
Genoa, 100 t.; Libau, 15 c.

TANNIC ACID—
Punta Arenas, 1 cs. (pt.), £14.

TAR (SWEDISH)—
Buenos Ayres, 1 t. 19 c.

TARTARIC ACID—
Amsterdam, 10 c., £155.; Bom-
bay, 1 c. (F.), £11.; Bombay,
12 c., £211.; Brussels, 1 c., £20.;
Busreh, 1 c., £17.; Fremantle,
2 c., £46.; Karachi, 7 c. (F.),

£61.; Paris, £485.; Pernambuco,
£20.; Shanghai, £135.; Singa-
pore, £360.; St. Lucia, £15.;
Wellington, £226.

WOOD PRESERVATIVE—
Pt. Elizabeth, £33.

ZINC OXIDE—
Des Moines, £230.

ZINC SULPHATE—
Beyrout, 2 cks., £7.

MANCHESTER.

Week ending October 1.

ALUM (LUMP)—
Montreal, 17 tes.

ALUMINA ACETATE—
Rotterdam, 1 brl.

ALUMINA SULPHATE—
Ghent, 62 cks.

ALUMINA SULPHOCYANIDE—
Rouen, 4 cks.

AMMONIUM CARBONATE—
Gothenburg, 115 pkgs.

AMMONIUM MURIATE—
Rouen, 22 drms.

ANTIMONY SALTS—
Rotterdam, 2 cks.

BARIAL SULPHOCYANIDE—
Boston, 4 cs.

BLEACHING POWDER—
Gothenburg, 409 cks.

BORAX—
Rotterdam, 20 bgs.

COAL PRODUCTS (otherwise undes.)
Alexandria, £1,055.; Antwerp,
£21,037.; Ghent, £247.; Genoa,
£18.; Gothenburg, £341.; Mel-
bourne, £547.; Philadelphia,
£678.; Rouen, £2,256.; Rotter-
dam, £395.; Sydney, £4,950.;
St. John, £11.

COAL PRODUCTS—
Nigrosine
Rotterdam, 1 kg.

DISINFECTANTS (otherwise undes.)
Rotterdam, 6 cks.

DYESTUFFS—
Logwood Extract
Rotterdam, 4 cks.

GLUE—
Boston, 1 cs.

LEAD NITRATE—
Antwerp, 8 cks.

MAGNESITE (CALCINED)—
Rouen, 100 bgs.

PITCH—
Antwerp, 187 t.

SALT—
Ghent, 4,000 bgs.; Gothenburg,
1,965 bgs.; Malmö, 3,947 pkgs.

SIZE—
Gothenburg, 4 cks.; Rouen, 1 ck.

SOAP—
Antwerp, 335 cs.; Montreal,
24 cks.

SODA ASH—
Montreal, 200 cks.

SODIUM BICARBONATE—
Gothenburg, 130 bgs.

SODIUM PRUSSATE—
Montreal, 5 cks.

SODIUM SULPHIDE—
Rouen, 121 pkgs.

SULPHUR—
Gothenburg, 22 bgs.

SULPHUR (BLACK)—
Rotterdam, 4 kgs.

TANNIC ACID—
Rotterdam, 4 cks.

MIDDLESBROUGH.

Week ending October 4.

AMMONIUM CARBONATE—
Antwerp, 3 t. 4 c., £205.

AMMONIUM SULPHATE—
Kobe, 548 t., £10,181.; Yoko-
hama, 50 t., £978.

BARIAL BINOXIDE—
Dieppe, 28 t., £3,238.; Yoko-
hama, 1 t., £138.

BARIAL CARBONATE—
Delagoa Bay, 1 t., £15.

BENZOLE—
Antwerp, 16,973 galls., £1,651.;
Dieppe, 25,755 galls., £2,575.

COAL PRODUCTS—
Disinfectants
Durban, 2,250 galls., £282.

Naphthalene
Dieppe, 30,459 galls., £3,186.

GLUE—
Antwerp, 10 t., £670.

MAGNESIUM CARBONATE—
Dieppe, 10 t., £391.; Rouen,
10 t., £391.

SALAMMONIAC—
Antwerp, 19 c., £72.

SALT—
Antwerp, 400 t., £1,330.; Sarps-
borg, 1,123 t., £2,809.

SODIUM SILICATE—
Cairo, 5 t. 3 c., £65.

TOLUOL—
Dieppe, 2,588 galls., £232.

NEWCASTLE-ON-TYNE.

Week ending October 4.

ANTIMONY—
Gothenburg, 2 t.; Montreal,
17 t.; Rotterdam, 69 t.

CAUSTIC SODA—
Gothenburg, 10 t.; Rotterdam,
90 t.

FERRO MANGANESE—
Gothenburg, 50 t.

GELATINE—
Bergen, 1 c.

RED LEAD—
Gothenburg, 10 t.; Montreal, 7 t.

SODIUM SILICATE—
Gothenburg, 18 t. 1 c.

SODIUM SULPHITE—
Gothenburg, 1 t.

SULPHUR—
Gothenburg, 62 t.

SULPHUR (ROCK)—
Rotterdam, 10 t.

WHITE LEAD—
Rotterdam, 2 t.

N. & S. SHIELDS.

Week ending October 4.

BITUMASTIC SOLUTION—
Malmö, 1 t. 1 c.

CAUSTIC SODA—
Malmö, 18 t. 12 c.; Norrköping,
5 t.; Stockholm, 26 t. 15 c.

STOCKTON-ON-TEES.

Week ending October 4.

NIL.

SWANSEA.

Week ending October 4.

NIL.

PRICES CURRENT.

THURSDAY, Oct. 9, 1919.

PREPARED BY MESSRS. HIGGINBOTTOM AND CO., 21, SPRING GARDENS, MANCHESTER.

The values stated are F.O.R. at makers' works, or at usual ports of shipment in U.K., unless otherwise specified
The prices in different localities may vary

Acids:—

		S.	d.
*Acetic 40% and 60%	per cwt.	30/-	& 45/-

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers) ..	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

EDITORIAL NOTICES.

Readers are invited to forward items of intelligence, company reports and balance-sheets, or cuttings from local newspapers of interest to the trades concerned.

Articles, reports, and correspondence on all matters of interest to the chemical and allied industries, home and foreign, are solicited. Correspondents should condense their matter as much as possible, write on one side only of the paper, and in all cases give their names and addresses, not necessarily for publication. Sketches should be sent on separate sheets.

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than Wednesday morning.

CURRENT TOPICS.

INDUSTRIAL ALCOHOL.

THE impetus which the railway strike has given to mechanical road transport ought to compel our new Ministry of Ways and Communications to give serious attention to the question of industrial alcohol. The mechanical transport and chemical industries know well enough the mass of evidence which exists as to the practicability of using industrial alcohol. It was used in Germany long before the war for agricultural internal-combustion engines, and a valuable series of experiments was carried out in this country by Dr. W. R. Ormandy which demonstrated that the difficulties of application to all forms of mechanical transport could easily and quickly be overcome. The only real drawback is the reluctance of the authorities to exempt from Excise duty alcohol used for industrial purposes. That is the one barrier which has to be overcome; all that remains then would be to solve the few remaining technical difficulties attaching to the production of alcohol and its extensive use in internal-combustion engines. At the British Association meeting, at Bournemouth, this year, Dr. Thaysen made out a very good case for the production of alcohol from mangolds, and there are many other means in various parts of the Empire by which alcohol could be produced from local materials. In the early days of the controversy it was alleged that certain products in Africa, which grow in large quantities, could be used as the basis of alcohol manufacture for industrial purposes at a cost of 3d. per gallon, a figure of course, which would not apply to-day. Nevertheless, it is quite clear that industrial alcohol could be produced at a figure which would be bound to have an important influence upon the price of petrol and benzole. The need for taking this question up and keeping the claims of alcohol to the fore does not rest entirely

upon the increased field for mechanical road transport, which the ravages of the war have created and the railway strike has accentuated. There is the far greater danger that the authorities, and particularly the Excise authorities, will be lulled into a sense of false security by certain extravagant hopes which are being raised by the finds of natural oil, such as they are, in this country. It is suggested, in quarters which we cannot help feeling ought to have shown more caution, that the recently discovered Derbyshire supplies and the oil to be obtained from the Norfolk shale will meet the whole of the home demand for motor fuel in this country. There is an absolute lack of figures to prove this assertion, and as things are at present there is bound to be a reliance placed upon imported oil for many years to come, and that must necessarily remain at a relatively high price. The benzole producers are business people, and naturally are not out to cut prices against imported petrol, and with the limited output there is a ready market for it at a price not much below that of petrol. The writer in question even allowed himself the satisfaction of the speculation that Great Britain may even be an oil-exporting country before many years. With the rapidly expanding field for the use of oil, and the knowledge that the sources of foreign supplies of petroleum oils are not increasing, it will not do to overlook any possible source of home-made fuel, and in spite of the supplies of benzole and the possible supplies from low-temperature carbonisation, the advocates of the use of alcohol, who have already done so much work, should see to it that this fuel is not preemptorily set aside by a wave of misplaced enthusiasm over home supplies of other forms of fuel.

TRADE RETURNS.

THE incidence of the railway strike in the closing days of last month is certain to have had some effect on the trade returns for September, but the extent to which the volume of British foreign trade has been influenced during the period under review must not be exaggerated. When the October returns are issued it will be found that the trade during the current month will bear the major portion of the loss resulting from the stoppage of railway transport. Last month's figures are anything but inspiring. Imports, valued at £148,625,000., are, it is true, slightly less than in August, but compared with September, 1918, they represent an increase of over £50,000,000.; whilst the exports, valued at £66,500,000., are £26,000,000. more than in the corresponding period of last year, but £8,273,000 less than in August. In the case of imports, much larger arrivals of foodstuffs and raw materials are responsible for the greatly increased returns compared with a year ago, the imports of manufactured goods showing but a comparatively small increase. On the export side, improved shipments of manufactures were to a large extent responsible for the increase over the returns of September, 1918. The position of the overseas trade in chemicals and allied products is still a fluctuating one. Exports of chemicals, drugs, dyes, and

colours were valued at £2,075,842., against £1,758,687. in the corresponding month of last year, an increase of £317,000. Compared with August, however, last month's value represents a drop of nearly £400,000. The shipments of sulphate of copper were reduced from 1,539 tons in September, 1918, to 61 tons; crude glycerine, from 1,860cwt. to 310cwt.; soda ash, from 324,497cwt. to 196,082cwt.; sodium bicarbonate, from 42,563cwt. to 40,253cwt.; caustic soda, from 112,795cwt. to 106,633cwt.; sodium sulphate, from 80,666cwt. to 29,029cwt.; and chemicals, other sorts, a decline in value from £468,708. to £381,897. The principal increases on the export side were in the case of bleaching powder, from 6,173cwt. to 23,028cwt.; distilled glycerine, from 3,560cwt. to 5,590cwt.; sulphate of ammonia, from 493 tons to 11,609 tons (chiefly to France, the Dutch East Indies, and Japan); superphosphates, from 530 tons to 819 tons; basic slag, from 71 tons to 2,112 tons; chemical manures, unenumerated, from 2,874 tons to 3,533 tons; muriate of ammonia, from 2,805cwt. to 10,405cwt.; white lead, from 1,594cwt. to 13,090cwt.; zinc oxide, from 284cwt. to 1,273cwt.; painters' colours and materials, unenumerated, from 38,940cwt. to 90,158cwt.; saltpetre, from 2,224cwt. to 3,728cwt.; chromate and bichromate of potash, from 42cwt. to 1,752cwt.; potash compounds, other sorts, an increase in value from £1,938. to £7,172.; chromate and bichromate of soda, from 4,505cwt. to 6,973cwt.; soda crystals, from 459cwt. to 5,798cwt.; soda compounds, other sorts, from 60,163cwt. to 60,822cwt.; sulphuric acid, from 339cwt. to 1,363cwt.; and tartaric acid, from 84cwt. to 723cwt. The imports of chemicals, drugs, dyes, and colours during September were valued at £2,125,285., against £3,535,038. in the corresponding month of 1918, a decrease of £1,410,000. Last month's value is approximately £350,000. more than the August total of £1,773,000. The most notable decline was in the value of the imports of "chemicals, unenumerated" (including acetate of lime, acetone, muriate of ammonia, and sulphuric acid). Imports of acetic acid dropped from 7,592cwt. to 4,601cwt.; sulphur, from 102,040cwt. to 986cwt.; cream of tartar, from 2,085cwt. to 460cwt.; crude glycerine, from 1,656cwt. to "nil"; saltpetre, from 39,159cwt. to 2,000cwt.; soda compounds, from 11,765cwt. to 2,765cwt.; chemicals, unenumerated, from £2,209,317. to £135,638.; and zinc oxide, from 5,557cwt. to 4,902cwt. The increases were chiefly confined to boracite, borate of lime, etc., from 8,675cwt. to 34,576cwt.; carbide of calcium, from 16,161cwt. to 31,164cwt.; coal products, not dyes, from 428cwt. to 1,818cwt.; potash compounds, other sorts, from £68,382. to £140,663.; tartaric acid, from 1,560cwt. to 2,189cwt.; barytes, from "nil" to 33,426cwt.; nickel oxide, from "nil" to 2,000cwt.; white lead, from "nil" to 20,149cwt.; and painters' colours and pigments, unenumerated, from 6,075cwt. to 49,644cwt.

DERBYSHIRE OIL.—It is stated that the flow of oil at Hardstoft Well, Chesterfield, has increased to over 2,000gals. per twenty-four hours, and at times shows considerable energy. Pumping has not been resorted to.

INDUSTRIAL POISONING IN CHEMICAL MANUFACTURE.*

Review of War Years.

By T. M. LEGGE, C.B.E., M.D.†

(Concluded from page 388.)

TOXIC JAUNDICE.

IN November, 1915, toxic jaundice occurring in a factory or workshop, and due to tetrachlorethane or nitro- or amido-derivatives of benzene or other poisonous substance, was added to the list of diseases in section 73 of the Factory and Workshop Act, 1901, of which notification is obligatory on medical practitioners and occupiers. The effects of tetrachlorethane when used as a dope in the manufacture of aeroplanes, and the high standard of ventilation which it was felt necessary to maintain even after the elimination of tetrachlorethane from the dope, have been described in detail in previous reports. This high standard was necessary in consequence of the continued use of benzole and acetone substitutes. In one factory where, owing to pressure of work, certain women had to carry on doping of the ordinary kind in a room provided only with natural means for ventilation, in a short time medical aid had to be summoned in consequence of symptoms of intoxication in some of them.

In last year's annual report I summarised the salient points in connection with T.N.T. poisoning. This has been the only source of cases of toxic jaundice included in the returns since the use of T.C.E. in dope ceased. It should be remembered, however, that a distinctive symptom in poisoning by arseniuretted hydrogen is jaundice, but in order to avoid confusion with cases of toxic jaundice from T.N.T. they have been, as they well can be, included under arsenic poisoning. In view of the description given last year, I merely make comparison of the figures due to T.N.T. in the three years.

Year.	Quarterly Periods.				Total.
1916	6 ³	16 ⁵	73 ²¹	86 ²²	181 ⁵²
1917	83 ¹²	56 ²⁰	21 ⁸	29 ⁴	189 ⁴⁴
1918	13 ⁴	6 ²	5 ²	10 ²	34 ¹⁰

The principal numbers relate to cases, the small figures to deaths.

One case (fatal), and that dating back to 1918, as regards employment, has been reported in the first five months of this year.

DINITROPHENOL.

In the French shell-filling factories, T.N.T. was not used to the same extent that it was in this country, being replaced by a mixture of picric acid and dinitrophenol. Experience in France showed in the first two years of the war that D.N.P. was highly toxic in the absence of care and cleanliness. By August, 1916, 27 deaths had occurred in seven factories using it, of which 17 occurred in weighing out the compound and melting it, eight in the process of hydro-extracting, one in stoving, and one in conditioning. In addition, numerous slight cases were treated. The health conditions and chemical reactions of the compound in the body were carefully investigated, with the result that a urinary test—the so-called Derrien reaction—was discovered, which served

both qualitatively and quantitatively to determine the amount of the poison absorbed, and so to give clear indication, provided the urine of each man was examined every day, when suspension and transference to other work was necessary.

The preventive measures adopted in France included close medical supervision of the workers by a daily visit from a surgeon and examination of the urine of every worker by a pharmacist. Every worker in whom the Derrien reaction remained positive for several days and increased in intensity was examined each day and suspended as soon as slight symptoms of intolerance showed themselves—gastro-intestinal trouble, lassitude, sweating, and liver or renal symptoms. Naturally, cleanliness of the skin, protection against dust and fumes by locally applied exhaust ventilation, and alternation of employment, also played their part.

When it became necessary in this country in 1918 to use D.N.P. in two factories, the late Lt.-Col. O'Reilly, C.M.G., R.A.M.C. (to whose unremitting efforts in the prevention of T.N.T., tetryl, and other forms of industrial poisoning at Woolwich Arsenal I desire to bear testimony) visited the principal factories in France, and as a result of his advice, very complete safeguards were established. The men employed were provided with a complete set of underclothing and overalls, into which they changed from their working clothes in a separate cubicle provided for each man. Locally applied exhaust ventilation of very perfect design was applied in the melting of the compound to take away the fumes, and in the filling of the 12in. shells. Any dust that collected around the margin of the shell was removed by a vacuum cleaner. The washing and bath-room facilities were all that could be desired. As a result of these measures, combined with daily examination of the urine, no trouble of any kind was experienced in the use of D.N.P. One fatal case, with typical symptoms, occurred in this country in 1916 in a factory where it was made.

FUMES AND GASES.

Below is a statement of the number of cases in 1917 and 1918 reported as accidents due to escape of gas, and for comparison those in 1913 and 1914. As already stated, cases due to arseniuretted hydrogen gas have been included under arsenic poisoning.

	1913.	1914.	1917.	1918.
Carbon monoxide	59 ⁷	62 ⁹	99 ¹⁸	54 ¹³
(a) Blast furnace	20 ³	20 ⁶	22 ⁶	17 ³
(b) Power	21	21	32 ⁸	21 ³
(c) Coal	9 ⁴	7 ¹	20	10 ⁴
(d) Other	9	14 ²	25 ⁴	6 ³
Carbon dioxide	12 ¹	3 ¹	1	5 ⁵
Sulphuretted hydrogen	8 ¹	22 ³	11 ⁴	7 ¹
Sulphur dioxide	1	1	2	1
Chlorine	1	2	3	4
Nitrous fumes	—	9 ²	62 ⁵	27 ⁷
Ammonia	3	4 ¹	4 ¹	6 ¹
Benzole, naphtha, and petrol	6 ²	4 ²	4 ²	7 ⁴
Tetrachlorethane	—	25 ⁴	—	—
Ether, acetone	—	—	4	1

The conditions of gassing in ordinary factories differ from those of chemical warfare, in the fact that they are

* Abstracted from the Annual Report for 1918 of the Chief Inspector of Factories and Workshops.

† H.M. Medical Inspector of Factories.

occasional and that protective appliances are needed for a time estimated usually by minutes and not hours. The need on the part of the workers, therefore, to avail themselves of the apparatus provided, and the employer to maintain it in a state of constant efficiency, is not considered to be so urgent as in the latter, where life is always in jeopardy. With the formation of Safety Committees in factories, gassing accidents should receive more attention than they have in the past. Persons should be made responsible for maintenance of the rescue appliances in proper condition, and regular drill in the use of them practised by foremen and workers alike. The best type of apparatus has still to be found for accidental escape in the repair of plant in which irrespirable or poisonous gases are present, during inevitable and unforeseen exposure to poisonous fumes and gases for short periods in repairing or cleaning stills, retorts, tank waggons, fermenting tanks, and for rescue work. Too often workers are found using respirators against nitrous fumes which are of no value whatever. The use of simple means, such as a folded handkerchief, is to court disaster. The worker must be equipped with a special mask or air helmet supplying him with fresh outside air, or else a self-contained oxygen breathing apparatus, making him independent of his surroundings. Probably the box respirator used in chemical warfare will find a useful place in certain chemical works. In all forms of reviving oxygen apparatus rubber is used largely for the connections. This perishes in the presence of acid gases and from lack of use, so that careful supervision is necessary to maintain it in a state of constant efficiency.

Nitrous Fumes.—A large number of cases, which must, however, only represent a small proportion of the actual number that occurred, arose directly out of the war in the manufacture of nitric acid and the subsequent nitration processes in the manufacture of explosives. In 1918 the cases had fallen largely as compared with 1917, when no fewer than 22 arose in the nitric acid plant, and 25 with five deaths in the manufacture of picric acid, tetryl, or tri-nitro-toluene; 10 were due to nitrating gun-cotton; four with one death to the bursting of carboys containing nitric acid; and three with one death to amalgamating with mercury the lead interior of three new pre-wash tanks, the solution used being mercuric nitrate. In the last case verbal instructions had been given to dilute the nitric acid with four or five times its volume of water, the object being to add sufficient water so that fuming during the preliminary washing over of the tank with nitric acid would not take place. With a weak solution, however, more labour was entailed in cleaning the tank, and the stronger the mixture the more easily could the work be done. Two men worked alternately as there was not sufficient room inside the tank for the two to work together. In this case, a suction fume pipe which operated with a compressed air ejector was not being used, as it should have been, during the repair work.

Nitrous fumes enveloping a workman for a period of one or two minutes leads to intense constriction in the throat, violent respiratory efforts are made, and the man becomes more or less collapsed. Exposure for more than two minutes will cause asphyxiation and death. Exposed for from one half to nearly two minutes the men rapidly recover on returning to the open air and soon feel as if the danger had passed. These are the cases in which, some hours later, distress is felt and often terminate fatally with œdema of the lungs. Workers daily

experiencing small escapes of nitrous fumes frequently have coughs with relaxed throat, and chronic bronchitis.

Early in the war a memorandum and placard on the precautionary measures to guard against nitrous fumes in the acid plant and nitrating sheds, as to the use of air helmets, use of oxygen cylinder, artificial breathing, and treatment in cases of gassing by nitrous fumes was circulated to occupiers of existing plants, and those in course of erection for the manufacture of picric acid, T.N.T., tetryl, and the like.

Benzole.—Benzole poisoning occurs in acute and chronic form. The following are instances of acute poisoning:

A man was employed as a stillman and succumbed to inhalation of benzole vapour, which had escaped into the benzole house owing to an increase of pressure on the steam boilers causing a quicker distillation of the vapour than the condenser was capable of dealing with. Consequently the vapour passed through the top of the intermediate receiver into the room. The man was first overcome on the evening of March 18. Artificial respiration had to be resorted to and oxygen administered. He revived, but became unconscious shortly afterwards. After repetition of the treatment for about two hours he again revived. Notwithstanding this, he returned to work on the evening of the 19th, and apart from a slight headache stated that he felt quite well, and worked throughout the shift. He returned again on the evening of the 20th, but died during the night; there was no direct evidence of any further gassing.

In another instance a man entered a benzole tank waggon through a manhole 16 inches in diameter to remove sediment. The tank had been filled with water, and steamed out for over 20 hours. The water was then run off, the tank refilled with cold water and boiled from 7 to 7 o'clock next day. Finally, after emptying, the tank was filled with cold water to cool it. The cold water was run off, and the tank stood about 10 days with the manhole open. A lad who was deputed to watch outside saw the deceased collapse. He got into the tank but found he could not assist him to get out, and summoned help. A man without hesitation went into the tank and fastened a rope round deceased. A rope had been provided, but deceased had not put it round him. The rescuer then collapsed. A third man at once went into the tank and managed to get them both out before he felt serious ill effect. In consequence of this fatality Mr. Jackson (North-Western Division) recommended: (1) Thorough boiling out with water, the mud being raked over at the same time; (2) filling and emptying with water immediately before entry; (3) provision of a respirator giving an air supply from outside the tank while anyone is inside it.

A somewhat similar accident, though not fatal, occurred in the cleaning out of a deposit of naphthalene at the bottom of a tank waggon used for bringing creosote oil (for use as fuel) from tar distilleries to a waggon works. In this case very similar instructions were given by Mr. Younger (Halifax).

Ether Intoxication.—Several cases of ether intoxication occurred in the manufacture of cordite with a mixture of ether and alcohol, which was used as a solvent instead of acetone. In nearly all the cases the effects were transitory. In the early stages of the manufacture, before the recovery plant in the stoves was perfected and women entered the stoves full of ethereal vapour, the attacks were sufficiently alarming. So much so was this

the case that their place had to be taken by men, who did not suffer to the same extent.

PITCH ULCERATION.

By an arrangement with the occupiers of the principal factories in South Wales for the manufacture of briquettes, reports have been obtained of cases of pitch ulceration, in several epitheliomatous in nature, which came to their knowledge. These cases were usefully followed up by inquiry by the certifying surgeon, so that for the years 1914-1918 particulars have been received of 64 men who have been affected, some of them more than once in the time stated. This is a very disappointing result, following on the inquiry which was made by Mr. A. H. Lush in 1911, and again in 1913, into the need for regulations requiring washing and bath accommodation, overall suits, prevention of dust, and protection against injury to the eyes.

The two factories in which by far the most satisfactory arrangements for washing accommodation and supervision of the workers have been made account for 44 of the 64 cases reported. These works employ the largest number of workers, and the high proportion in them is due to the closer supervision exercised by the management, resulting in the reference for treatment of all cases of warts found. For this reason also the cases reported from them are of slighter severity than from the others.

The nature of the work is to grind material first to powder before compressing the pitch and fine coal dust into blocks. Improvements made to reduce the excessive dust have not been very successful. Great difficulty is experienced in maintaining the conveyor casings dust-proof, and in addition it has to be borne in mind that the mixture of pitch and coal is of an explosive nature. The percentage of men using the baths is very small and is mostly confined to the younger men, who are not necessarily those most exposed to the dust. The percentage of men who change their clothing before going home is also very small. No really satisfactory preparation has yet been found for allaying the irritation of the dust on the skin. Dusting with starch powder or fuller's earth is used by some to relieve the burning and irritation on exposure to wind and sun, which is noticeable particularly after washing. In addition to the pitch warts, particulars were received of four cases of ulceration of the cornea due to pitch dust, involving in one case complete loss of sight. Crêpe or goggles are worn by some men, but not universally.

In addition to the epitheliomatous condition in pitch works information was received of eight cases contracted either in tar works or by workers coming in contact with tar between 1914 and 1918. Four were reported as severe, suffering from epithelioma of the scrotum, two of which proved fatal, and one from epithelioma of the forearm, requiring amputation, in a man aged 60 engaged in net-making and so handling tar. An exactly analogous malady arises in the refining of paraffin as carried on in the five shale-oil works in Scotland.

INDUSTRIAL DERMATITIS.

Dr. Bridge investigated the condition known as oil dermatitis which proved very troublesome in a large number of engineering works during the war, arising from the cutting oils, cutting compounds, and soluble oils used on automatic lathes and similar machines, and composed chiefly of mineral oil derived from the residue of petroleum left after distilling other oils which boil below 300° C. The malady has been known for a long

time, having been described, with typical illustrations, in a paper by Dr. H. S. Purdon, in 1902, on "Acneiform Eruptions in Flax Doffers in Belfast." The condition, Dr. Bridge says, closely resembles that seen in the green or paraffin sheds of the shale-oil refineries, but is milder in form. He describes the affections of the skin due to oil in engineering shops as, first, inflammation of the hair follicles (folliculitis or peri-folliculitis); secondly, septic infection; and, thirdly, eczema.

Injury to the skin is the primary factor in the production of septic infection, and as lubricating fluids contain fine, sharp particles in suspension, mere movement of the fingers or leaning the arms on the work may produce sufficient injury to the skin as to cause the primary lesion, through which the germ enters. For prevention, cleanliness of the workers' hands and arms, and the removal of the oil and dirt, unavoidably present, is essential. Dr. Bridge describes as having proved satisfactory not only in prevention, but also in curing the condition, washing with ether soap and powdering the arms before and after work with equal parts of zinc oxide and starch.

Numerous inquiries into outbreaks of eczema arising out of conditions due to the war were made. It is remarkable how many of them were due to derivatives of coal tar, petroleum, and shale oil, used as explosives or dyes (tetryl, picric acid, T.N.T., nitrosophenol), and, therefore, probably due to the same essential cause as pitch and petroleum acne. Generally, the substances setting up industrial eczema are, first, chemical irritants and caustic agents like bichromate of potash and arsenious acid and certain finished dyes; secondly, those which dissolve and remove the natural grease from the skin, such as turpentine, petroleum benzine, benzene, and its homologues, and the intermediate bodies their nitro- and amido-derivatives; thirdly, processes which soften and macerate the skin, such as alkalis; and, fourthly, processes which mechanically injure the continuity of the skin, such as brushing, scratching, and rubbing. With the oily and greasy material removed, the dry skin cracks, and the most important thing in prevention is to try to restore, as far as possible, the natural lubricant to the skin.

If irritating powders are handled—and this has been especially brought out in connection with the use of tetryl, in the handling of which hardly any workers escaped an initial incapacitating attack of dermatitis,—much the best preventive during work was found to be dusting the skin with a dry powder, such as talc and starch, rather than the use of an ointment, which tended to collect and retain the noxious powder. The spread of eczema from the hands to other parts of the body indicates that the pathogenic germs on the skin have set up a septic infection.

Dr. Bridge and Mr. Verney (North London) investigated an outbreak of eczema in which 40 to 50 cases had occurred within 15 months of the starting of the manufacture of phenacetin in what Mr. Verney described as "an old and unsuitable building, too small for the plant, and ventilated only through the door and by openings in the roof and near the eaves." Seeing the conditions of manufacture, Dr. Bridge found it difficult to arrive at the exact cause, but believed that the intermediate products and acids used led to a drying of the hands with subsequent cracking and the formation of vesicles; while the phenol vapour accounted for an acute erythema and swelling of the face occurring so rapidly as within an hour completely to occlude sight.

ACID RESISTING IRON

MR. E. L. RHEAD, in the course of a lecture on Tuesday on "Inherent Faults in Metallic Materials used in the Construction of Chemical Plant"—the first of a series of twenty lectures on chemical engineering subjects arranged by the Department of Applied Chemistry of the College of Technology, Manchester,—referred at some length to the characteristics of cast-iron.

In the case of cast-iron vessels used in chemical manufacture very serious results were frequently produced. Flakes of graphite formed channels by means of which the corroding liquid or gas penetrated the metal and brought about somewhat rapid corrosion. To illustrate this point the lecturer referred to some nitration pans which had been in use for some considerable time before being employed for nitration purposes. A good deal of corrosion had already taken place, but directly they were put on the more strenuous work of nitration the pans failed. An examination showed that the interior of the metal pans had been penetrated by the corroding liquid along the faces of the flakes of graphite, and had produced corrosion on both sides of those flakes. For acid-resisting cast-irons of the ordinary type it became necessary, in order to secure the best results, to keep to as close a grained iron as possible. The graphite also should be as small in quantity, and in as small flakes as it was possible to obtain. The larger the graphite flakes the greater the degree of attack that was likely to occur. Many of the heavy types of chemical vessels were being made with cast-iron containing a low percentage of silicon, the reason being to reduce the size of the graphite flakes and to avoid laying the metal open to attack. That referred to ordinary cast-irons.

Dealing with acid-resisting irons with a high silicon content, these were known under various names, and contained from 9 to 18 per cent. of silicon, the proportion varying with the make, and to some extent, said the lecturer, with the purpose for which the particular plant was to be employed. Those materials had been very largely used in the concentration of sulphuric and nitric acids during the period of the war, and they had given satisfactory results in the majority of cases. The life of the materials, however, varied very considerably. It had fallen to his lot to investigate the causes of the differences in the behaviour of the irons. In one particular case the material had been made into very large and expensive plant, and was found to be unsatisfactory, and to be giving out very quickly. The surface of the metal was very deeply pitted, and the cause of the corrosion was located as being due to the presence in the material of a considerable proportion of phosphorus in the form of phosphide. The phosphide in this material segregated with greater ease than it did in the case of ordinary iron. The fact that the phosphide component of the iron was responsible for the corrosion was made out as the result of a very careful investigation. All high-silicon irons that are used for the protection of acid-resisting materials should be free from phosphides, and also free from sulphur. Sulphur behaved in an unsatisfactory manner, and where it was concentrated the corroding influences were very strongly marked. The physical condition of acid-resisting materials had a great deal to do with the resistance that they offered. The right kind was the one that showed a fine grain and no sign of chilling.

At the opening meeting of the Manchester Metallurgical Society, on Tuesday evening, Mr. Rhead read a paper entitled "Notes on the Resistance of Iron and Iron Alloys to Chemical Action," which, in substance, was similar to the lecture reported above.

Mr. S. McCraith, who opened the discussion, said it was usually considered that a small percentage of copper in steel had a marked effect in preventing corrosive influences.

Mr. S. Evans stated that in his opinion corrosion was not a simple chemical action. There were probably two or three types of corrosion, and whether the chemical one was the most important and the most common was not definitely settled. With water cooling, corrosion in nitrate pots was cut down. Porcelain, he said, was a good deal more satisfactory for nitration than cast-iron. Regarding the effect of vibration on wrought iron as affecting its corrodibility, there was no doubt, he said, that it had a bad effect. The effect was to make the iron crystallise, and the growth of those crystals could be very plainly seen. The resulting channels then formed the lines of least resistance for the corrosion to take place.

Mr. W. Wilson said he was much interested in the remarks concerning phosphide segregation. There was no doubt that chemical segregation and the acceleration of corrosion went hand in hand. Referring to Mr. McCraith's remarks, the speaker said that a small percentage of copper undoubtedly had an inhibitive effect upon corrosion. Up to 0.3 per cent. in ordinary mild steel had a good effect in preventing corrosion from acids.

AMERICAN IMPORT DUTIES ON ZINC AND ZINC COMPOUNDS.

A BILL (H.R.6238) which has passed the United States House of Representatives, and is now before the Senate, proposes to amend as follows the Customs import duties on zinc ores and manufactures thereof, with a view to establishing and maintaining their production in the United States:—

Classification.	Rates of Duty.	
	Present.	Proposed.
Zinc-bearing ore of all kinds, including calamine:—		
Containing less than 10 per cent. of zinc	10 % ad val. on zinc content	Free
Containing 10 per cent. or more and less than 20 per cent. of zinc		½ cent per pound on zinc content.
Containing 20 per cent. or more and less than 25 per cent. of zinc		1 cent per pound on zinc content.
Containing 25 per cent. or more of zinc		1½ cts. per pound.
Zinc in blocks or pigs, and zinc dust	15 % ad val.	1½ cts. per pound.
Zinc in sheets	15 % ad val.	1½ cts. per pound.
Zinc in sheets, coated or plated with nickel or other metal, or solutions of zinc, old and worn-out, fit only to be re-manufactured		1 cent per pound.
Zinc, oxide of, and white pigment containing zinc, but not containing lead:—		
Dry	10 % ad val.	1 cent per pound.
Ground in oil	15 % ad val.	1½ cts. per pound.
Sulphide of zinc, white, or white sulphide of zinc	15 % ad val.	1½ cts. per pound.
Chloride of zinc and sulphate of zinc	½ cent per pound	1 cent per pound.

PERMEABILITY OF PAINTS AND VARNISHES.

THE first meeting of the session of the Oil and Colour Chemists' Association was held in London on October 9, Mr. H. H. Morgan presiding. A paper was read by Mr. A. de Waele entitled "Notes on the Permeability of Paints and Varnishes."

A year or two ago the author carried out a series of experiments to determine the relative porosity of various paints in respect both to their media and to their pigment-to-medium proportion, with the result that for any given pigment the proportion of spirit-free medium to 100 parts of pigment was found to be inversely proportional to the porosity. When comparing different pigments it was also found that intrinsic impermeability for a given proportion of pigment to medium was also influenced inversely as the specific oil absorption of the pigment. Oil absorption is referred to as that minimum proportion of oil necessary to convert the dry pigment into an unmistakable paste. A little consideration would show, said the author, that on physical grounds only such behaviour was to be expected, thus ruling out the possibility of any chemical influence. Films of paint were obtained by coating tinned iron, allowing several days for thorough drying, and then amalgamating with mercury and dilute sulphuric acid one edge of the sheet. In the course of a few hours amalgamation had proceeded sufficiently to peel off the sheet. It was necessary to examine microscopically the film worked on, and also to carry out determination in triplicate, but contrary to expectations, very rarely did accidental pinholes occur. Varnish films were similarly obtained. Determinations of permeability were obtained by introducing into a flat-lipped CO_2 flask a little strong H_2SO_4 , coating round the lip with a molten mixture of shellac and resin, applying the film, trimming off, and weighing when cold. The flask was then kept in an incubator in a saturated atmosphere, and weighings were made every three hours. Experiments were also made to determine the actual nature of the "pores" in varnish films, and it was obvious that they were not microscopic. The author's experience having shown that while a varnish film was free from obvious imperfections, such as cracks due to age, absolute adequate protection against rust was afforded no matter how porous the film might appear on the permeability determinations; it rather suggested that the degree of permeability was in the nature of the film being a semi-permeable membrane. Experiments in this direction gave results which conflicted with generally accepted laws.

Reference was also made to the behaviour of varnishes made on a tung-oil basis, having regard to the extraordinary absence of "bloom", or "chalking" on immersion of such a film in water. No differences were apparent, however, in the osmosis experiments between copal varnishes, both hard-drying and elastic types, and varnishes made with china-wood oil quite free from tendency to bloom. The author was in charge of the A.I.D. paint and varnish laboratory, and owing to disparity in results occasionally arising as to the degree of opalescence of oil-varnish films when immersed in distilled water, experiments were made which resulted in a piece of sheet tin coated with a flat-drying or semi-gloss black stoving enamel being used as a substratum in preference to glass or wood. The author was not prepared to offer any explanation as to the non-chalking of certain films of china-wood oil varnish on immersion,

but uttered a warning that although blooming may be condemnatory in an oil-varnish film, non-blooming must certainly not be taken as a criterion of its ability to withstand water. Finally, contrary to the experience of many, the author has found little difference between immersion in salt or distilled water.

Mr. A. Selby Wood, who opened the discussion, said that practical experience in the past had indicated that tung-oil varnish was more suitable for conditions where there was moisture or water, such as boat varnish, but if he understood the lecturer's experiment aright there did not seem to be much difference between the permeability of a china-wood oil and a tung oil film.

Mr. A. Molteni asked as to how the author judged rusting. Very often, although a metal appeared to be non-rusting with the film on it, when the film was removed there were signs of corrosion, although perhaps it could not be called rusting. He could not offer an explanation of this. (The author said he could not either.) Mr. Molteni also referred to an experiment on a very thin wood-oil film which appeared to be very resistant to moisture. He exposed it for about three months in a moist atmosphere, but there appeared to be no signs of rusting. It was then placed in the laboratory, and after two months the whole thing corroded very badly.

Mr. W. J. Palmer called attention to the fact that the pigment entered into this question of permeability as much as the medium, and American-published results took this into consideration more than seemed to be the case in this country. He believed the effect was a joint action of the pigment and medium, at any rate, so far as paints were concerned. The theoretical considerations were obscure, but there must be a theoretical basis.

Mr. J. B. Dampney asked for data concerning the relative resistivity of tung-oil varnish and ordinary varnish.

Mr. Tyson said he had found that polymerised linseed oil, burnt umber, and carbon black made an admirable protective coating for corrugated iron. Some iron painted with this material had been in use at his firm's works for nine years satisfactorily, notwithstanding the proximity of a chemical factory, a soap works, and a match factory.

Mr. J. G. Wilkinson said he had been trying permeability experiments on a small scale, and asked for more information as to their manipulation, particularly with regard to the preparation of the films. So far he had been using filter paper, coated with gelatine, and soaking in water, which was fairly satisfactory. Another question was as to the effect of the thickness of the films.

The Chairman said that he himself started some experiments of the nature referred to in the paper about 12 or 18 months ago, but they were not yet completed. When the results were obtained he would publish them if they seemed of any value. Many attempts had been made to determine the permeability of varnishes on wooden blocks. That method was often adopted in this country and in America, the wooden blocks being varnished, weighed, and then immersed in water or subjected to a moist temperature, and the increase in weight noted. For practical purposes, when varnishes were used on wood that was as good a method as any, because it reproduced, as near as possible, practical results. A large number of experiments of this nature were carried out by the British Engineering Standards Committee when drawing up the specification for the Air Board in connection with propeller varnishes. Such

experiments, however, had to be carried out very carefully, but very often they were not. He agreed that the pigment played a very vital part in protective paints, and he was pleased to hear that there was little difference shown in the author's experiments between tung-oil varnish and linseed-oil varnish. It would have been useful if that fact could have been established some years ago.

Mr. de Waele, replying to the discussion, said that he had found tinned steel was best in enabling a judgment to be arrived at as to rusting, the tin accelerating the rusting. In answer to Mr. Wilkinson, he said he did not measure the thickness of the film, but attempted to get the same thickness by working on varnishes of approximately equal gravity and equal viscosities as far as possible, *i.e.*, containing the same amount of volatile solvent.

Mr. de Waele then read a short paper entitled "A Suggested Method for Calculating the Cost of Ready-Mixed Paints," but time prevented him going into it in great detail. He pointed out that cases often arise in practice when it is necessary to make calculations as to the cost of a paint of a given tint, but actual preparation of samples is difficult owing to lack of time, etc. Often, also, in the attempted cheapening of certain paints by substitution of inert filler for white lead or other pigment base, some revision of formula is necessary in consideration of higher or lower oil absorption due to the substitution. The paper was an attempt to work out a method which would permit of such calculations without the necessity of recourse to the roller mill or the laboratory cone mill, both of which often afford inaccurate or insufficient information. The principal stumbling-block in the calculation of paint formulae is the amount of medium to be used to obtain a given fluidity or ease of working, and a number of examples were worked out. On employing the formulae for various pigments and mixtures of pigments it has been found that paints of equal fluidity are obtained by adding an equal volume of thinner to the volume of the paste.

BRUNNER-MOND'S SOAP INTERESTS.

LEVER BROS.' PURCHASE.

THE directors of Messrs. Brunner, Mond and Co., Ltd., issue the following statement to their shareholders under date of October 8:—

"In view of the many and inaccurate reports recently circulated in financial circles, the directors of Brunner, Mond and Co., Ltd., desire it to be known that they have to-day concluded an agreement to sell to Lever Brothers, Ltd., the ordinary shares in Joseph Crosfield and Sons, Ltd., soapmakers, Warrington, and William Gossage and Sons, Ltd., soapmakers, of Widnes, which were acquired by Brunner, Mond and Co., Ltd., in the year 1911. The sale was made at a price which the directors consider is a fair one, and is payable in cash.

"In conveying this information to their shareholders, the directors desire to say that although this rearrangement of investments will obviate the necessity for any issue of capital for some considerable time, yet they see no reason to anticipate that the rearrangement will cause any increase in the amount of profits previously earned by the company, or the amount available for distribution."

It is reported from Liverpool that the price paid by Lever Brothers to Brunner, Mond and Co. for the

acquisition of the ordinary shares in the two companies is four millions.

PHOSPHATIC FERTILISERS.

AT a meeting of the Institution of Mining and Metallurgy at Burlington House, London, on Thursday, Mr. F. D. Powers read a paper on "Coral Island Phosphates in the Making." In the course of his remarks the author stated that the oxides of iron and alumina are objectionable in the manufacture of super-phosphates, as they not only consume sulphuric acid, but if the mixed oxides exceed 4 to 4½ per cent. they are liable to form an objectionable gelatinous precipitate, which by coating some of the phosphate particles prevents the acids from reaching them. Yet these phosphates of iron and alumina are not necessarily useless when applied to certain soils in the raw state, for, in addition to the carbon dioxide transpired from the rootlets of plants, there is also the process of fermentation of the organic matter present to assist in its decomposition, while the rôle played by the various kinds of bacteria is known to be an extremely important one. McGeorge, in the *Hawaii Agricultural Experimental Station Bulletin* 41, shows that, in sand cultures with millet, ferric and alumina phosphates produced more vigorous plants than acid phosphate, sodium phosphate, phosphate rock, or Thomas slag. In the *Rhode Island College Experimental Station Bulletins* 114 and 118 it is stated that phosphates of iron and alumina when dehydrated by roasting gave better results than ground Florida phosphate, and the effect was increased by the addition of slaked lime. Carlton C. James (*Jour. Ind. and Eng. Chem.*, Jan., 1918), referring to the views held by some that reverted phosphate is of less value than acid phosphate, states, "Considering the results obtained here by an acid phosphate which has been reverted, we are inclined to believe that under certain conditions prevailing in Hawaii, reverted phosphates give the better results." Again, "We have found in numerous cases that the reverted phosphate is just as valuable or even more valuable than the water-soluble when applied to cases upon upland soils. These soils are, as a rule, highly ferruginous clays. On soils which have not been cropped for several years, the reverted phosphate gives excellent results."

Tri-calcium phosphate when applied raw must be finely ground. It is insoluble in water, but as it slowly comes in contact with the roots of plants, it is converted into mono-calcium phosphate, $\text{CaH}_4(\text{PO}_4)_2$, which is soluble in water. In contact with the lime of the soil, it is transferred into di-calcium phosphate, but by that time it is so uniformly divided that the organic acids generated by plants render the compound suitable for their assimilation. In this way the beneficial effects of the phosphate would not be apparent until at least after the end of the first year.

Finely ground raw calcium phosphate cannot be applied to all types of soil with equal success. The most suitable is that of an acid nature, or those which are rich in humus, or are wet and peaty. It may be of very little use in light soils. It will thus be seen that whether phosphates reach the soil naturally, or are applied artificially, the nature of the soil over which they travel will have a large influence in deciding as to whether they are taken up by plant life on land or are carried out to sea. Earthy calcium phosphates, such as fine guano, are more suitable for direct application to soils than crystalline forms.

BRITISH OVERSEAS CHEMICAL TRADE IN 1918.

(Continued from page 391.)

WE give below extracts from the annual statement, just issued, of the trade of the United Kingdom with foreign countries and British Possessions in 1918, compiled by the Customs and Excise Department. The figures relating to the chemical and allied trades will be found much more useful than those given in the monthly Board of Trade returns, owing to the detailed analysis of the countries of origin of imported, and the destinations of exported, chemical products. Each product is specified separately, together with the extent of the trade done with the more important countries, the corresponding figures for 1917 being in parentheses.

IMPORTS.

Guano.—Uruguay, — (1,034 tons); other foreign countries, — (268 tons); Falkland Islands, — (1,299 tons); total, — (2,601 tons).

Manures, Unenumerated.—Norway, 839 tons, valued at £2,774. (1,300 tons, £15,600.); Argentine Republic, 86 tons, £1,384. (582 tons, £6,220.); other foreign countries, — (767 tons, £11,298.); British Possessions, 22 tons, £741. (60 tons, £1,280.); total, 947 tons, £4,899. (2,709 tons, £34,407.).

Cochineal.—Canary Islands, 373cwt. (289cwt.); other foreign countries, 249cwt. (168cwt.); British Possessions, — (59cwt.); total, 622cwt. (516cwt.).

Cutch.—Foreign countries, 25cwt. (115cwt.); British India, 31,444cwt. (27,640cwt.); Straits Settlements, 14,469cwt. (1,676cwt.); British Borneo, 13,029cwt. (18,082cwt.); other British Possessions, 400cwt. (—); total, 59,367cwt. (47,513cwt.).

Alizarine and Anthracene Dyestuffs.—Foreign countries, 1,995cwt. (41cwt.).

Aniline and Naphthalene Dyestuffs.—Germany, — (1cwt.); France, 29cwt. (43cwt.); Switzerland, 39,397cwt. (45,848cwt.); United States, 5,233cwt. (7,089cwt.); other foreign countries, 4cwt. (1cwt.); total, 44,668cwt. (53,052cwt.).

Synthetic Indigo.—Switzerland, 2,084cwt. (9,894cwt.); China, — (44cwt.); other foreign countries, — (2,028cwt.); total, 2,084cwt. (11,966cwt.).

Other Coal-tar Dyestuffs.—Foreign countries, 219cwt. (397cwt.).

Extract for Dyeing.—France, £18,235. (£147,152.); Italy, £250. (—); United States, £157,916. (£388,541.); other foreign countries, £12,338. (£64,514.); British West Indies, £594,524. (£496,872.); other British Possessions, — (£5,704.); total, £783,263. (£1,102,783.).

Indigo.—Java, 187cwt. (804cwt.); San Salvador, 123cwt. (320cwt.); other foreign countries, 31cwt. (82cwt.); British India, 4,946cwt. (12,254cwt.); other British Possessions, — (41cwt.); total, 5,287cwt. (13,501cwt.).

Dyestuffs, Unenumerated.—France, 21,589cwt., valued at £77,367. (31,980cwt., £112,037.); Algeria, 423cwt., £2,260. (1,538cwt., £5,951.); Switzerland, — (103cwt., £853.); Portugal, 21,664cwt., £73,805. (24,445cwt., £81,908.); Spain, 39,013cwt., £199,420. (73,305cwt., £258,978.); Italy, 64,900cwt., £296,156. (43,439cwt., £184,805.); United States, 681cwt., £5,589. (501cwt., £3,489.); Argentine Republic, 701cwt., £3,635. (289cwt., £1,443.); other foreign countries, 12,964cwt., £58,692. (1,047cwt., £3,479.); Cape of Good

Hope, 4,980cwt., £13,323. (6,106cwt., £14,400.); British India, 2,127cwt., £11,123. (7,605cwt., £15,255.); other British Possessions, 7,549cwt., £36,203. (243cwt., £690.); total, 176,591cwt., £777,573. (190,601cwt., £683,288.).

Soap Stock.—United States, — (224cwt.); other foreign countries, 560cwt. (—); British Possessions, 325cwt. (670cwt.); total, 885cwt. (894cwt.).

Soft Soap.—Foreign countries, 43cwt. (—).

Household and Laundry Soap.—France, 440cwt. (1,728cwt.); Italy, — (2,249cwt.); United States, — (19cwt.); other foreign countries, 16cwt. (—); British Possessions, 120cwt. (116cwt.); total, 576cwt. (4,112cwt.).

Soap Powder.—Foreign countries, — (30cwt.); British Possessions, 16cwt. (—); total, 16cwt. (30cwt.).

Toilet Soap.—Germany, — (4cwt.); France, 1,653cwt. (820cwt.); United States, 13cwt. (321cwt.); other foreign countries, 116cwt. (56cwt.); British Possessions, 2cwt. (7cwt.); total, 1,784cwt. (1,208cwt.).

Soap, Unenumerated, including Cottonseed Oil Soap.—Foreign countries, — (8cwt.).

Antimony Ore.—China, 50 tons (—); Chili, 1,213 tons (5,890 tons); Bolivia, 5,971 tons (8,608 tons); Argentine Republic, 1,064 tons (1,003 tons); other foreign countries, 488 tons (959 tons); British East Indies, 2 tons (128 tons); Australia, 5 tons (1,612 tons); Canada, 24 tons (273 tons); other British Possessions, 100 tons (853 tons); total, 8,917 tons (19,326 tons.).

Antimony, Crude and Regulus.—France, 224 tons (61 tons); China, 846 tons (2,498 tons); Japan, 1,197 tons (2,425 tons); other foreign countries, 2 tons (67 tons); British Possessions, 335 tons (407 tons); total, 2,604 tons (5,458 tons).

Copper Ore.—Norway, — (72 tons); France, 90 tons (158 tons); Portugal, 1,240 tons (1,523 tons); Portuguese East Africa, 215 tons (370 tons); Spain, 43 tons (—); Peru, 102 tons (117 tons); Chili, 491 tons (2,292 tons); Bolivia, 10,866 tons (2,049 tons); other foreign countries, 251 tons (976 tons); Cape of Good Hope, 234 tons (779 tons); Transvaal, 1,487 tons (7,202 tons); Rhodesia, 300 tons (1,009 tons); Australia, — (7 tons); total, 15,319 tons (16,554 tons).

Copper, Regulus and Precipitate.—Portugal, 2,095 tons (924 tons); Portuguese East Africa, — (434 tons); Spain, 8,419 tons (10,239 tons); United States, 1,470 tons (2,606 tons); Mexico, — (3,559 tons); Peru, 65 tons (152 tons); Chili, 239 tons (411 tons); Bolivia, 66 tons (207 tons); other foreign countries, — (100 tons); Cape of Good Hope, 315 tons (5,173 tons); Transvaal, 118 tons (199 tons); Canada, 8,226 tons (4,227 tons); other British Possessions, — (7 tons); total, 21,013 tons (28,238 tons).

Lead Ore.—France, — (107 tons); Spain, — (138 tons); Peru, 108 tons (2,180 tons); Chili, 727 tons (580 tons); Argentine Republic, — (1,688 tons); other foreign countries, 227 tons (661 tons); British India, 14 tons (2,050 tons); Australia, 421 tons (—); other British Possessions, 5 tons (1,253 tons); total, 1,502 tons (8,657 tons).

Lead, Pig, and Sheet.—Spain, 49,977 tons (36,268 tons); Italy, — (3,506 tons); Greece, 1,253 tons (—); United States, 61,576 tons (10,084 tons); other foreign countries, 2,323 tons (1,424 tons); British India, 2,338 tons (1,720 tons); Australia, 85,280 tons (93,654 tons); other British Possessions, 5,185 tons (468 tons); total, 207,932 tons (147,124 tons).

Manganese Ore.—Russia, 2,231 tons (2,137 tons); Portuguese India, 2,541 tons (3,128 tons); Spain, 816 tons (1,710 tons); Japan, 1,449 tons (1,937 tons); other foreign countries, 460 tons (4 tons); Gold Coast, 29,510 tons (21,720 tons); British India, 324,338 tons (300,500 tons); other British Possessions, 4,261 tons (128 tons); total, 365,606 tons (331,264 tons).

Platinum, Wrought or Unwrought.—France, 596 troy oz. (632oz.); United States, — (2,716oz.); other foreign countries, 362oz. (—); British Possessions, 265oz. (458oz.); total, 1,223oz. (3,806oz.).

Pyrites of Iron and Copper.—Norway, 112,889 tons (49,960 tons); Portugal, 28,003 tons (31,096 tons); Spain, 695,811 tons (772,585 tons); Italy, — (600 tons); total, 836,703 tons (854,241 tons).

Quicksilver.—France, — (770,760lb.); Spain, 772,805lb. (399,350lb.); Italy, 304,275lb. (880,945lb.); other foreign countries, 380lb. (122,379lb.); total, 1,077,460lb. (2,173,434lb.).

Tin Ore.—Netherlands, — (9 tons); France, 29 tons (78 tons); Portugal, 132 tons (554 tons); Spain, 3 tons (49 tons); United States, — (2 tons); Peru, 28 tons (311 tons); Chili, 7,528 tons (16,944 tons); Bolivia, 15,992 tons (14,048 tons); Argentine Republic, — (16 tons); other foreign countries, 307 tons (307 tons); Nigeria, 8,123 tons (8,756 tons); British South Africa, 5 tons (54 tons); Straits Settlements, 33 tons (25 tons); Australia, — (34 tons); other British Possessions, 150 tons (21 tons); total, 32,330 tons (41,208 tons).

Zinc Ore.—Netherlands, — (25 tons); France, 413 tons (813 tons); Algeria, 24,066 tons (27,411 tons); Spain, 39,596 tons (15,705 tons); Italy, 13,661 tons (21,916 tons); Tunis, 6,673 tons (4,232 tons); Japan, 10 tons (441 tons); United States, — (73 tons); other foreign countries, 4,979 tons (510 tons); Australia, 3,359 tons (16,054 tons); Canada, 30 tons (—); other British Possessions, — (188 tons); total, 92,787 tons (87,368 tons).

Zinc, Crude, in Cakes.—Norway, 5,591 tons (3,246 tons); Netherlands, 15 tons (2,693 tons); Belgium, 4 tons (—); France, 9 tons (83 tons); Japan, 7,051 tons (17,905 tons); United States, 50,495 tons (51,091 tons); other foreign countries, 79 tons (368 tons); Australia, — (439 tons); New Zealand, — (17 tons); Canada, 815 tons (194 tons); other British Possessions, 79 tons (69 tons); total, 64,138 tons (76,105 tons).

Methylic Alcohol.—United States, 66,939 gallons (190,736 gallons); Canada, 249,952 gallons (149,021 gallons); total, 316,891 gallons (339,757 gallons).

Barytes.—Spain, 21,700cwt. (20,615cwt.); United States, 7,904cwt. (1,945cwt.); other foreign countries, — (5,419cwt.); total, 29,604cwt. (27,979cwt.).

Nickel Oxide.—United States, 4,231cwt. (7cwt.); Canada, 15,342cwt. (23,601cwt.); total, 19,573cwt. (23,608cwt.).

Red Lead.—Netherlands, — (60cwt.); United States, — (2,255cwt.); total, — (2,315cwt.).

White Lead.—United States, 4,568cwt. (51,718cwt.); other foreign countries, 2cwt. (—); Canada, 40cwt. (—); total, 4,610cwt. (51,718cwt.).

Zinc Oxide.—Netherlands, 1,494cwt. (58,103cwt.); Belgium, — (1,871cwt.); France, 402cwt. (5,231cwt.); United States, 76,090cwt. (133,871cwt.); other foreign countries, 1,800cwt. (2,549cwt.); total, 79,786cwt. (201,625cwt.).

Painters' Colours and Pigments, Unenumerated.—Germany, 34cwt. (487cwt.); Netherlands, 26,081cwt. (128,541cwt.); France, 34,042cwt. (39,458cwt.); Spain,

38,462cwt. (34,786cwt.); Italy, 7,401cwt. (8,014cwt.); United States, 75,105cwt. (98,474cwt.); other foreign countries, 1,123cwt. (2,068cwt.); Cyprus, 630cwt. (1,534cwt.); British East Indies, 41cwt. (89cwt.); Canada, 3,520cwt. (5,784cwt.); other British Possessions, 29cwt. (418cwt.); total, 186,468cwt. (319,653cwt.).

Paraffin Wax.—Netherlands, — (21,220cwt.); Dutch Indian Possessions, 6,000cwt. (4,208cwt.); United States, 1,035,291cwt. (1,335,745cwt.); other foreign countries, 5,500cwt. (6,650cwt.); British India, 116,911cwt. (85,013cwt.); other British Possessions, 958cwt. (—); total, 1,164,660cwt. (1,452,836cwt.).

Pitch, other than Coal Pitch.—Russia, 19,151cwt. (27,248cwt.); United States, 2,545cwt. (10,907cwt.); other foreign countries, 1,701cwt. (3,768cwt.); total, 23,397cwt. (41,923cwt.).

Rosin.—France, 316,124cwt. (297,284cwt.); Portugal, 49,985cwt. (58,865cwt.); Spain, 17,574cwt. (68,129cwt.); United States, 365,496cwt. (1,302,276cwt.); other foreign countries, 1,958cwt. (—); British Possessions, 1,286cwt. (4cwt.); total, 752,423cwt. (1,726,558cwt.).

Salt, Rock and White, except Table Salt.—Portugal, 204 tons (732 tons); Spain, 500 tons (158 tons); total, 704 tons (890 tons).

Talc, French Chalk, Steatite, Mineral White, Silica, and Soapstone.—France, 268,773cwt. (185,289cwt.); Italy, 28,433cwt. (40,605cwt.); United States, 3,386cwt. (24,832cwt.); other foreign countries, 3,060cwt. (4,748cwt.); British Possessions, — (224cwt.); total, 303,652cwt. (255,698cwt.).

Tallow, including Vegetable Tallow, Unrefined.—France, 18,359cwt. (11,270cwt.); China, 2,559cwt. (26,683cwt.); United States, 124cwt. (2,132cwt.); Uruguay, 44,124cwt. (13,949cwt.); Argentine Republic, 177,356cwt. (27,411cwt.); other foreign countries, 1,200cwt. (6,277cwt.); Australia, 113,668cwt. (328,508cwt.); New Zealand, 42,168cwt. (190,025cwt.); other British Possessions, 3,256cwt. (4,044cwt.); total, 402,814cwt. (610,299cwt.).

Tar, other than Coal Tar.—Russia, 52,593cwt. (85,001cwt.); Sweden, 450cwt. (1,241cwt.); United States, 8,929cwt. (60,467cwt.); other foreign countries, 3,000cwt. (—); total, 64,972cwt. (146,709cwt.).

Varnish, not containing Spirit.—Germany, — (89 gallons); France, 185 gallons (3,264 gallons); United States, 1,068 gallons (79,634 gallons); other foreign countries, — (2,213 gallons); total, 1,253 gallons (85,200 gallons).

Vinegar and Acetic Acid (for table use).—Netherlands, — (229 gallons); France, 19,331 gallons (38,825 gallons); United States, 5,410 gallons (14,861 gallons); other foreign countries, 300 gallons (—); British Possessions, 9,398 gallons (698 gallons); total, 34,439 gallons (54,613 gallons).

(To be continued.)

POSSIBLE STATE MONOPOLY FOR GERMAN MATCH INDUSTRY.—The question of the establishment of a State monopoly for the German match industry was recently discussed at Weimar. The sum of 120,000,000 marks has been mentioned as being necessary for indemnifying the factory owners; this figure, however, merely represents a provisional estimate. While the Government apparently agree that the transformation of the match industry into a State monopoly would be comparatively simple and would not involve any appreciable industrial disturbance, they apparently feel that the matter is not urgent. It is suggested that the law which might eventually be passed as a result of the present discussions should only go into effect on March 31, 1921. In the meantime there would be ample opportunity to take any preparatory steps which might be necessary.—U.S. Com. Rep.

CHEMICAL TRADE OF SOUTH AFRICA.

ACCORDING to the annual report of Mr. J. L. Wilson-Goode (H.M. Trade Commissioner at Cape Town) on the trade of South Africa in 1918, paints and varnishes to the value of £24,634. were produced locally in the year 1915-16, and to the value of £46,421. during 1916-17. It is estimated that the South African market for paints and distempers approximates in point of value to £250,000. a year. The production of chemicals increased in value from £119,000. in the year 1911, to £171,040. in 1915-16, and to £234,494 in 1916-17. The chief chemicals produced in the Union are: Acids (sulphuric, nitric, hydrochloric, carbonic), alcohol, ammonia, argol, arsenic, bisulphate of soda, bleaching powder, disinfectants, epsom and glauber salts, glycerine, saccharine, sodas, starch and starch flour, and nitrate of lead.

A guncotton explosive, manufactured in Natal, which is known as "Sengite," is a production to which considerable attention has been devoted. It is possible that this article will become a permanent explosive, but the permanency or otherwise depends on future relative prices of glycerine and cotton. At any rate, during the period of the war, it can claim to have lessened the demand for glycerine and to have provided against the possibilities of a serious shortage of that article.

The present demand for cement in the Union is in excess of the local supply, but the ability to produce greater quantities is receiving considerable attention.

The demand for fertilisers is becoming increasingly felt in South Africa, but although considerable deposits of phosphatic rock exist at Saldanha Bay, the progress in this direction has not been very rapid owing to the difficulty of converting the insoluble iron and alumina phosphate into a form available for fertilising purposes. No doubt fertilisers will be manufactured to a much larger extent in the near future, but the importation of a considerable quantity of ingredients will be necessary for some time to come.

There are eight principal industries in the Union whose annual production in 1915-16, in each case, exceeds one million pounds sterling, and in some cases runs into several millions. Following these, in order, are: Soap, £382,000.; candles, £626,000.; tanning, £475,000.; distilleries, £382,000.; oil and grease, £272,000.; cement, £270,000.; fertilisers, £170,000. Among the new industries which have been initiated are those which concern the production of the following articles: Calcium carbide, chloride of lime, alcohol motor fuel, wattle bark extract, starch, glue and size, tinning of iron plates, disinfectants and dips, shoe and floor polishes, sulphate of ammonia, paints and distempers from local materials, raw wax from by-products of sugar cane, lead shot and pellets, antimony smelting, arsenic, and asbestos.

IMPORTS.

The imports of drugs and chemicals from the United Kingdom are far in excess of those obtained from any other country, and are approximately four-fifths of the total imports into South Africa. Before the war the importations from Germany were on a very large scale, being approximately three-fifths of the quantity imported from the United Kingdom. The United States had a small share of the trade, which she maintained during the period of hostilities, but, having regard to the advance of prices, it is probable that the importation from the United States has not increased to any

appreciable extent. Canada, Japan, and Australia have entered the market, and in some lines their position will probably be retained.

The value of the imports of perfumery in 1913 was £65,836., of which the United Kingdom contributed £32,408., America £20,944., and France £8,402. In 1918 the imports were valued at £162,466., of which the United Kingdom contributed £68,014., and America £68,542. The imports from France were valued at £23,100. Values have been considerably increased, and it is therefore not unlikely that the quantity imported shows a reduction as compared with pre-war importations.

Practically all the supplies of castor oil are drawn from India and the United Kingdom, although Portuguese East Africa sent supplies to this market during the year 1916. The trade in cocoanut oil is divided between India, Mauritius, and Zanzibar, the supplies from other countries, with the exception of Ceylon and Portuguese East Africa, being on a very small scale. With regard to linseed oil the total imports in 1913 were 421,246 gallons, of which the United Kingdom supplied 418,179 gallons. In 1918 the total quantity imported was 413,426 gallons, of which the United Kingdom only supplied 7,379 gallons. On the other hand, India, who entered the trade in 1916, supplied no less than 179,469 gallons, and the Argentine Republic supplied 175,297 gallons, although they did not hitherto send supplies to this market. The imports from the United States were 37,488 gallons, and from Canada 11,452 gallons. It is desirable, however, from the point of view of comparison, to quote the 1917 figures, which are entirely different. The total importations that year were 218,134 gallons, of which the United Kingdom supplied 184,058 gallons, India, 26,462 gallons, and the United States 7,608 gallons. In the year 1915 and 1916 practically the whole of the supplies was drawn from the United Kingdom. Perhaps there is no trade in which such remarkable changes have taken place as in the supply of linseed oil.

During the last two years supplies of paints, colours, and varnishes from the United Kingdom, which were on a large scale before the war, and reached a record figure in 1916, have been reduced, and America and Canada have taken the opportunity of supplying paints, varnishes, and leads, but, with the exception of American paints and leads, this competition is only regarded as temporary, the quality of the importation from these countries being inferior to the British articles and the packages of awkward dimensions. It is believed, therefore, that this trade will revert to the United Kingdom.

The restrictions placed upon the manufacture and export of certain articles, hitherto supplied by the United Kingdom, and the resultant diminution of British trade with South Africa, are mainly responsible for the increase in the trade of the United States and Japan during the war. Japanese imports into South Africa received a large measure of support as a consequence of the inclusion of the Cape ports in the itinerary of the ports of call for Japanese steamers. So far as America and Canada are concerned, neither of these countries has received encouragement from special banking, steamship, or distributing facilities. As a matter of fact, freights from the United Kingdom have been cheaper than from either of the countries named. In the case of America, the demand for cash for goods on delivery at the wharf, without guarantee of freight, compelled importers of American goods to lay out capital without any guarantee

of receiving the goods, and this arrangement constituted a restraint to American trade.

EXPORTS.

The quantity of wattle bark exported in 1913 was 145,717,738lb., valued at £309,329. In 1917 the quantity exported was reduced to 93,526,862lb., valued at £225,710, but in 1918 it increased to 107,904,898lb., valued at £287,220. There were no exports of wattle bark extract in 1913, but in 1917 the exports amounted to 2,784,188lb., valued at £49,520., and in 1918 to 8,339,459lb., valued at £124,887. Shortage of freight space has been mainly responsible for the reduction in the quantity of wattle bark exported during the war, but the local consumption has been on a larger scale as a consequence of the increased activities of the South African tanneries.

In 1913 the quantity of whale oil exported was 2,177,537 gallons, valued at £122,692., but in 1917 the exports were reduced to 212,659 gallons, valued at £16,410. In 1918 the quantity exported was 561,577 gallons, valued at £62,316. The large decrease in the exports during the war has been brought about by a combination of circumstances. In the first place, there has been a reduction in the number of firms operating; secondly, the consumption of whale oil by local soap works has largely increased; thirdly, the Government requirements of glycerine for use in the South African explosive factories have been considerable; and, lastly, there are large stocks of whale oil in the country for which permission to export to countries other than the United Kingdom was withheld during the war.

DUTCH CHEMICAL INDUSTRIES.

THE situation of the chemical industries of the Netherlands during the first half of 1919 must be considered unfavourable; in most establishments production has fallen considerably below the output for 1918; some of the largest works have closed down or are only partly in operation. The manufacturers of fertilisers suffer from the competition of imported Chili saltpetre, the stocks of which in the country are in excess of the needs of agriculture. General complaints are heard concerning difficulties of a financial character caused by the interference of the Netherlands Overseas Trust and the Netherlands Export Co., and delays in issuing export licenses. Although various raw materials have been ordered abroad, and there are no official objections to the importation, the manufacturers are still waiting in vain for shipments. The interests of these industries suffer also from the heavy fluctuations of prices which make the customers hesitate in placing orders unless an early delivery is assured. The trade pursues a policy of watchful waiting. Some dealers are still holding large stocks and trying to make sales abroad. The wide differences in the prices at which goods are offered add to the reluctance of the traders to buy.

The low exchange of the mark is of considerable importance at this time. Products of German origin are offered at prices which are noticeably lower than the prices of the raw materials, imported likewise from Germany, which are employed in the manufacture of those same products. Some chemical works have to face additional difficulties, as they are unable to export their products, while the raw materials and intermediate products can be imported from the territories of the Central Empires. For the chemical industries in general the outlook is dark. It is feared that the market may be glutted

with low-priced foreign goods, while the difficulties of exportation make impossible the sale of surplus products abroad, which is a vital question for the establishments concerned.—*U.S. Com. Rep.*

SCIENCE AND INDUSTRY.

METALLURGISTS AND A CHEMICAL BIAS.

THE subject of science and industry was discussed in his presidential address by Mr. F. C. A. H. Lantsberry, M.Sc., F.I.C. (Chief Chemist, Birmingham Small Arms Company, Ltd.), at the opening meeting of the Birmingham Metallurgical Society.

Engineers, industrial chemists, and metallurgists, said Mr. Lantsberry, might follow the noble example of Watt and determine what could be done for the immediate and future benefit of industries, rather than spend the time in preening themselves on the part played by their particular science in the winning of the war. In the past grave charges had been made as to the lack of business capacity on the part of the scientific man. He had upheld the reputed lack of commercial ability on the grounds that the man who possessed the true scientific spirit and business acumen was a *rara avis*, and generally speaking, the man who attempted to be both scientific and commercial became really efficient in neither. The present was an age of specialisation, for not only had a man to choose some particular branch of industry, but he had also to specialise in some section of that industry. The solution of the problem lay in sympathetic co-operation, and sympathetic co-operation was impossible between two experts who were each mutually ignorant of the other's subject. The time had arrived when more attention should, by all parties, be given to the acquisition of such scientific knowledge as might be obtained through the medium of technical societies.

Scientific knowledge would have to be more widespread before industry could take full advantage of the benefits to be derived from the application of scientific methods. The bulk of our large manufacturers had appreciated the value of scientific assistance to the extent of providing their works with well-equipped laboratories, but the efforts of those laboratories were hampered, and, in some cases, seriously hindered, by lack of appreciation of science on the part of the men with whom they had to deal. For the same reason other manufacturers who were in dire need of the assistance of a well-equipped laboratory hesitated to call in the assistance of investigators trained to work along proper lines.

When industrial conditions became normal, industry would have sore need of men with adequate scientific training. He was aware that at the present time men with high scientific credentials experienced difficulties in finding employment in their proper sphere, but he was convinced that this was a direct outcome of the unsettled condition of the country, which was not rapidly becoming "normalised."

The first essential in the training of a technical investigator was, Mr. Lantsberry insisted, that he should have a thorough groundwork in the fundamental principles of his own particular and allied sciences. He had known industrial chemists and engineers to make good metallurgists; but at the same time he was convinced that the best metallurgists had a strong chemical bias in their initial training, for chemistry was the subject *par excellence* for developing attention to detailed observation of phenomena.

LOW-TEMPERATURE CARBONISATION.

AT a meeting of the Scottish Junior Gas Association (Eastern Section) at Edinburgh, on Saturday last, a paper on "Low-Temperature Carbonisation" (an account of which appears in the current issue of the *Gas Journal*), was contributed by Mr. R. M'Laurin, the author dealing particularly with the low-temperature carbonisation process which bears his name. This process, he said, so far as he was aware, was the only true low-temperature process.

Dealing with the yields of gas in the various carbonisation processes, the author said that on a calorific basis one might be fairly safe in allowing for 6,000,000 B.Th.U. from high-temperature carbonisation, 4,500,000 B.Th.U. from semi-low-temperature carbonisation, and 2,500,000 B.Th.U. from low-temperature carbonisation. That is only when taking account of the gas evolved from coal on carbonisation. The total volume of unsaturated hydrocarbons escaping in the gas in high and semi-low-temperature processes per ton of coal is about the same; but in a true low-temperature distillation, they are only about one-sixth of the volume. The methane from high-temperature carbonisation is slightly greater in volume per ton of coal than for semi-low-temperature processes described. The high claims of the semi-low-temperature processes rest on the quality of the coke which can undoubtedly be produced. The weakness lies in the difficulty of making it continuously of uniform quality capable of standing transit. The smokeless fuel produced in the M'Laurin low-temperature process cannot correctly be termed a low-temperature product, nor even a semi-low-temperature product. It can only be correctly described as a semi-high-temperature product; for it has passed down through the producer zone, possibly reaching a temperature little short of that existing in a steamed vertical. The M'Laurin process, with its high-temperature coke, is more likely to prove a rival to the coke-oven than to the vertical retort. In many ways it resembles an elongated bee-hive oven with a by-product recovery plant installed. With the plant installed at Port Dundas, with its water-seal below, we obtained a smokeless fuel which occasionally sparked very badly when placed on a fire; and this difficulty could not be overcome without tearing down the whole of the plant. This, during the war, was out of the question. A smaller unit has been erected at Stirling, to obviate the necessity of wetting the hot fuel; and this has proved effective. The fuel produced in this is now thoroughly satisfactory in every way. In this plant we can at will produce smokeless fuel and metallurgical coke.

The sulphate of ammonia is the next most valuable constituent. The high-temperature liquors, besides their ammonia, contain cyanides, ferrocyanides, sulphocyanides, etc., and some phenolic bodies, for the most part unexamined, and which colour the spent liquors usually a reddish brown. A very fair average yield per ton of coal is 26lb. of sulphate of ammonia. For semi-low-temperature processes the yield is only about half the above—viz., 12 to 13lb. The M'Laurin process, so far as ammonia is concerned, is not a true indicator for the yields of low-temperature carbonisation, as the fuel is afterwards subjected to high-temperature and steam in the generator zone of the producer, and the ammonia given off on carbonisation. The yields, therefore, vary according to the time of steaming. Results, however, indicate that we get the ammonia given off on low-temperature carbonisation first, then the ammonia given

off on raising to a higher temperature, and finally a small proportion due to steaming. This proportion rises as the steaming is prolonged. Roughly, you may assume the sulphate of ammonia as running between 26 and 36lb. If the coal is burned to ash, however, it naturally rises even up to 60 or 70lb. per ton of coal; and if we were dealing with coals rich in nitrogen, possibly considerably higher. But this is not the result of low-temperature carbonisation.

The quantity of tar from high-temperature carbonisation varied from 6 to 12 gallons. From similar coals on semi-low-temperature carbonisation they would obtain 14 to 23 gallons, and low-temperature carbonisation would give about the same amount. The quality of the tars was, however, widely different. The high-temperature carbonisation contained the three primary cyclic compounds—benzene, naphthalene, and anthracene. A light naphtha gave benzene, toluene, and xylene. The anthracene oil contained anthracene and phenanthrene, etc. Among the phenolic bodies it contained carbolic, cresylic, xylenols, etc., very little, if any, naphthols, and some pyrocresols. They also contained a relatively small percentage of paraffins, olefines, and terpenes. The pitch contained bitumene and free carbons. The semi-low-temperature tars were reputed to contain paraffin wax, also paraffin olefins, and naphthalenes; and this kind were termed paraffinoids. The compounds were benzene, naphthalene, anthracene, bitumene, and free carbons, and the smallest percentage of carbolic. The true low-temperature oils differed in containing very complex phenols which dried readily on wood, so far as he could gather, differing from any known phenols. Distillation gave a whole series from 190° to 360° C., and the residue was still phenolic. Distillation destroyed the drying properties of these phenols. It had been impossible so far to work out a constitutional formula for any of them, owing to the difficulty of getting pure bodies. The paraffinoid portion contained paraffin waxes with a melting point about 48° C. The mass of the oil, however, was not really paraffinoid or olefines. Such oils would require to have carbon to hydrogen as 10 to 20 and 22, whereas the hydrogen present to 10 of carbon was about 16; and deducting for the paraffin present, it came down to 14. This brought it near to the turpentine or to cymenes. The boiling point of these paraffin oils ran about 360° C.; and it was difficult to find any hydrocarbons on boiling at this temperature. Paraffin was quite evident in the distillation, giving rise to the term paraffinoid. Little residue was left at the finish of the distillation, and what there was, was of a greasy nature. The distillation differed considerably from the original oil, indicating that they had been decomposing in the process. It was evident from this that these oils could not have passed through the regions of high temperature.

In the M'Laurin process the phenolic portion of the oil distilled-out or was washed-down; but on a semi-low-temperature vertical or Del-Monte type of plant, or in a high-temperature vertical or horizontal retort, the outside layer of coal was at 700° or 800° C. before the phenols were being distilled-out. Consequently they had to run the gauntlet of highly-heated carbon layers; and if they escaped destruction here, they had the heated walls of the retort to face before getting into the comparative safety of the draw-off pipe. Assuming that the complex phenolic bodies obtainable from low-temperature carbonisation were given off within the heart of such a piece of coal when it was reaching a temperature round about

360° C., the outer layer of red-hot carbon would not let these pass out with any oxygen attached, if it could help it. Therefore they should expect to find, as the external temperatures maintained increase, a gradual reduction in the complexity of the phenolic bodies and a steady increase in the proportion of hydrocarbons—possibly corresponding to the phenolic bodies deprived of their oxygen. This, he believed, correctly recorded what did happen. True low-temperature tars contained none of the simple aromatic compounds—such as benzene, toluene, naphthalene, anthracene; semi-low-temperature carbonisation contained some traces; but as the polyhydric phenols and complicated drying phenols disappeared, benzene, toluene, naphthalene, anthracene, phenanthrene, etc., appeared in the tar products. It was his opinion, therefore, that the coal itself contained the nuclei from which the cyclic compounds of the high temperature tars were largely made up, and only a small proportion (if any) was due to the condensation of acetylene or other similar unsaturated hydrocarbons. Resins were composed of phenolic compounds combined with complex alcohols or resino tannols. The phenols known were simpler than those they would have to assume as existing in coal; but this was not an unlikely supposition when they considered that some of the resins had sixty carbon atoms in their molecule. The phenolic bodies contained in resins were carboxy phenols such as

umbellic acid. Now when such acids were heated, they readily parted with CO_2 ; and the first gas given off on the low-temperature carbonisation of coal was CO_2 . Further justification for this assumption lay in the fact that some of the phenols extracted from his low-temperature ammonia liquors gave off CO_2 on heating to somewhere about 150° C. It was well known that pyrocatechol and chloroglucic acid were obtainable from the distillation of certain resins. Recent resins gave turpentine on heating a body containing 10 carbon atoms and 16 hydrogen atoms in the molecule. Turpentines readily polymerised; and it did not seem a great stretch of fancy to suggest that terpenic oil obtained by low-temperature distillation was the product of distillation of highly polymerised terpenes in the coal.

In the M'Laurin process, the heating of the coal was so slow and so uniform that the bulk of the lighter oils and gas were away before the softening of the resin began; and this again was so slow that it practically softened and hardened again *in situ* as it were. It was in this way that he accounted for the greater hardness of the high-temperature coke produced in his process. If the temperature was finally raised until the amorphous carbon was altered, then a very hard coke was obtained.

LEGAL INTELLIGENCE.

Chemical Import Restrictions: Application in Test Case.

In the Chancery Division on Tuesday, Mr. R. A. Wright, K.C., on behalf of Messrs. Brown and Forth, chemical manufacturers, London and Manchester, applied to Mr. Justice Younger to fix an early date for the trial without pleadings of their test action against Mr. Buckley, the Manchester Collector of Customs, which raises an important question as to the legality of a Royal Proclamation prohibiting the import of chemicals.

Counsel declared that the case was of the utmost importance not only to the plaintiffs, whose goods had been seized and detained, but also to traders generally. It raised the question whether it was possible to practice Tariff Reform by

Executive Act without express Parliamentary sanction. The plaintiffs had imported a quantity of pyrogallic acid, which was an ordinary commercial article used in photography. It was seized by the Collector of Customs at Manchester under the colour of a proclamation prohibiting the import of chemicals, and that proclamation purported to be issued under Section 43 of the Customs Consolidation Act, 1876. The case for the plaintiffs was that there was no power under the Act to issue such a proclamation or to prohibit the importation of ordinary articles of commerce, and they brought their action for a declaration that the seizure was entirely unauthorised and wrongful. When the matter came before the Vacation Court, Mr. Justice Greer showed considerable sympathy with the plaintiffs, and said he was inclined to think that their construction of the proclamation was right, but he was unable to finally decide so grave a question on an interlocutory application.

The Attorney-General (Sir Gordon Hewart, K.C., M.P.) opposed the application on the ground that every point raised by the plaintiffs could be taken by them on the proceedings already instituted by the Crown for the condemnation of the goods, which was the procedure prescribed by the Statute. If he assented to the application, he would be encouraging the setting-up of an entirely new system of trying revenue cases. The action was also misconceived because it was brought against a subordinate official who could not return the goods if ordered to do so. Under these circumstances he could not assist in expediting the trial of the action.

Mr. Wright urged that there should be a prompt trial. The seizure was made in August.

His Lordship said that in face of the opposition of the Crown he could not insist upon the action being set down for trial without pleadings. The plaintiffs must proceed in the ordinary way with pleadings.

Application to Wind Up Picric-acid Company.

Mr. Justice Astbury, in the Companies Winding-up Court of the Chancery Division, on Tuesday, heard a petition for a compulsory order to wind up Grays Chemical Works, Ltd.

Mr. Lavington, for the petitioner, Mr. G. T. Morgan, said he was a judgment creditor for £109., of which £50. was still owing. He was also a creditor for £75. arrears of salary.

For the company, it was stated by counsel that the whole of the assets were covered by securities held by the bank, and the evidence showed that there was nothing for unsecured creditors unless arrangements were carried through for raising new capital. The company was formed to manufacture picric acid for the Government, and that had now ceased. It was proposed to start another manufacture, for which new plant was needed.

His Lordship adjourned the petition, saying that in the face of the evidence he would not make an order. He wished to see what came of the negotiations that were going on.

OUR BOOK SHELF.

STEREO CHEMISTRY. By Alfred W. Stewart, D.Sc. Second edition. London: Longmans, Green and Co., 12s. 6d. net.

This book (one of the series of text-books of physical chemistry edited by the late Sir William Ramsay, K.C.B., F.R.S.) has achieved a second edition. Amongst the improvements, it will be found that the amount of space previously devoted to steric hindrance has been curtailed and utilised in other directions. A short chapter devoted to the Walden Inversion has been included. Section I., under the general heading, "Stereoisomerism in Carbon Compounds," covers ten chapters; Part II., "Stereoisomerism in Carbon Compounds Without Optical Activity," six chapters; Section II., "Stereochemical Problems Into Which Isomerism Does Not Enter," six chapters. Half this second edition consists of new or rewritten matter.

ELECTRIC SPARK IGNITION. By I. D. Morgan, A.M.I.C.E., A.M.I.E.E. London: Crosby, Lockwood and Son, 8s. 6d. net.

An account of the scientific basis of the subject of electric spark ignition in internal combustion engines, the ground covered being: Gas characteristics, spark characteristics, interaction of spark and gas, spark generator and characteristics. The book represents very useful work, and will be well received.

ITEMS OF INTEREST.

TINPLATE MANUFACTURE IN JAPAN.—It is reported, according to the *Japan Chronicle*, that the Yawata State Steel Works, in Kyushu, have for some time past been carrying on experimental work in the manufacture of tinplate, and the results are so promising that commercial manufacture is soon to be started and the product put on the market.

COLOUR WORKERS' WAGES.—An award has been issued of an arbitration into a claim for an advance of 10s. a week for men and 5s. a week for women engaged in the paint, colour, and varnish manufacturing industry of Great Britain. The court has awarded an advance of 4s. a week to men aged 18 and over, to apply to time workers and piece workers.

ZINC AND ZINC DUST PRICES.—Australian high-grade zinc dust (88-92% metallic zinc) continues very firm at £70. per ton c.i.f. U.K., inquiries being persistent for prompt supplies. The price of Australian electrolytic zinc, containing 99.95% metallic zinc, is unchanged at £42. per ton f.o.b. Australia for direct shipment to New Zealand, India, South Africa and the Far East.

BRUNNER-MOND'S NEW SECRETARY.—Messrs. Brunner, Mond and Co. announce that Captain Duncan Marsh has been appointed by the board of directors as the company's secretary, in succession to Mr. J. H. Gold, who was recently made a director. Before joining the Army Captain Marsh was a solicitor, and during the past few months has filled the position of acting-secretary to the company.

MALAY TIN EXPORTS.—It is reported by official cablegram from Kuala Lumpur that the export of tin from the Federated Malay States in September amounted to 3,161 tons, compared with 2,955 tons in August and 3,166 tons in the corresponding month last year. The total for nine months amounted to 28,261 tons, as against 28,336 tons in the corresponding period last year and 29,572 tons in 1917.

NON-FERROUS MINING.—The Committee appointed by the Board of Trade to consider and report upon non-ferrous mining in the United Kingdom held its first meeting after the recess on Monday, under the chairmanship of Mr. H. B. Betterton, M.P. It has decided to deal in the first instance with tin mining, and will proceed forthwith to take evidence. Subsequently the Committee will take up the question of zinc and lead mining.

CORROSION OF STEEL.—Steel is given resistance to rusting to an important degree by copper in amounts usually reported as only traces. In an investigation reported by D. M. Buck to the American Society for Testing Materials, increasing the proportion of copper from 0.01 to 0.03 per cent. decreased the corrosion by 30 to 40 per cent.; and with 0.15 per cent. of copper protection was given even to steel having a considerable excess of sulphur.

CHEMICAL WORKERS' WAGES.—An arbitration took place at Old Palace Yard, Westminster, on Monday afternoon on a claim by the Amalgamated Society of Pharmacists, Drug and Chemical Workers, for a general increase of wages based on various rates according to grade, skill and ability for men and women employed in the drug and fine chemical manufacturing trades. An application was also made for a reduction of working hours. The Court reserved its award.

CONTROL OF WORLD'S SUPPLY OF VANADIUM.—H.M. Acting Commercial Secretary at Washington says that according to a report published by the Standard Statistics Company, Messrs. J. Leonard Replogle (former Director of Steel Supplies) and Charles M. Schwab have bought the mines in Peru and the mills in Pittsburgh of the American Vanadium Company. This deal involves the control of about 98 per cent. of the vanadium supply of the world. The company, it is stated, will probably be known as the Vanadium Company of America.

INDUSTRIAL LEAGUE.—The annual dinner of the Industrial League will take place at the Connaught Rooms at 7 p.m. on October 22. The Rt. Hon. G. H. Roberts, M.P., President of the Industrial League will preside, and Lt.-Colonel John Ward, C.B., C.M.G., will be the principle guest. Since the last annual meeting the Industrial League has made considerable headway and recently amalgamated with the Industrial Reconstruction Council of which the Rt. Hon. J. H. Whitley, P.C., M.P., is President. A large number of employers from all parts of the kingdom are bringing workmen, shop stewards, foremen and managers to the dinner, and a record gathering is anticipated. The Secretary's address is, 66, Victoria Street, S.W.1.

PERSONAL.—Dr. M. O. Forster, F.R.S., has accepted office as Prime Warden of the City Guild of Dyers.

CUMBERLAND NITROGEN WORKS HELD UP.—At a meeting of the Derwent (Cumberland) Fishery Board on Monday, it was stated that the Nitrogen Products Company, who proposed to establish extensive works at Workington, and take water from the river Derwent, were not proceeding with the works owing to being unable to get a guaranteed coal supply. Mr. F. Hall (Mayor of Workington) read a letter, which stated that the company were not prepared to commit themselves to any expenditure till a thousand tons of coal per shift were guaranteed.

SCOTTISH OILWORKS RESTARTING.—Everything points to several of the Scottish oilworks being restarted at a much earlier date than had been expected. When the retorts at the various works were allowed to cool down it was feared that it might be well into November before work could be resumed. Last week the work of heating the retorts was started at Deans, and it is expected a start with similar operations will take place this week at Seafield. At Addiewell oilworks the candle factory has restarted, and a considerable number of the oil-workers have got employment effecting repairs at the various centres.

SPANISH PRICE OF QUICKSILVER FIXED.—The *Revista de Comercio y Hacienda*, in the issue of August 16 last, publishes a statement that the administration council of the Almaden mines at its session on August 12, taking into account the quotations of quicksilver in the London markets during the month of July and the average rate of exchange of the pound sterling, decided that the price for national industries of a flask of quicksilver of 34.507 kilos. (76lb.), effective on that date, shall be 451 pesetas (£17.) if delivery be taken at the mine, or 453 pesetas if placed aboard railway-car at the station of Almadenejas.

SALT, BROMINE, AND CALCIUM CHLORIDE IN THE UNITED STATES.—The quantity of salt produced and sold in the United States in 1918 was 7,238,744 short tons, valued at £5,400,000., an increase of 3.7 per cent. in quantity and 35.1 per cent. in value over the production in 1917. The bromine marketed in 1918 was 1,727,156lb., valued at £194,000., compared with 895,499lb. and £98,000. in 1917—an increase of 93 per cent. in quantity and of 97 per cent. in value. The calcium chloride output was 26,624 short tons, valued at £100,700., against 30,503 tons and £90,300. in 1917—a decrease of 12.7 per cent. in quantity and 11.5 per cent. in value.

ELECTRICAL CONDUCTIVITY OF SALT VAPOURS.—According to G. C. Schmidt, *Mitteilungen des Reichsbundes Deutsche Technik*, the vapours or the volatile halogen salts of cadmium, zinc, ammonium, iron, and aluminium are good conductors of electricity even at relatively low temperatures, whereas the vapours of the halogen salts of mercury, tin, antimony, arsenic, and iodine and other organic substances are insulators. The experiments show that the conductivity increases with time until a maximum is obtained and then falls to a constant value. Further tests, however, show that even at very high temperatures the conductivity of salt vapours is independent of time provided there is sufficient surface-constancy. The apparent inconstancy is caused by the fact that the vapours can only pass into the measuring-chamber gradually and later on the salts get caked together, thus reducing the surface and the rate of evaporation. The vapour density and ionisation also decrease.—*Technical Review*.

EXPLOSIONS.—A fatal still explosion occurred at the works of Messrs. L. B. Holliday and Company Limited, dye-makers, of Deighton, near Huddersfield, on Friday of last week, when the death of a workman and injury to another resulted. The two men—Isaac Brown and Joseph William Cheeseman, were testing the still when the explosion occurred. Brown received such severe injuries that he died almost immediately. Cheeseman, however was not so severely injured, and after treatment at the Royal Infirmary, at Huddersfield, was allowed to go home.—The story of three explosions at the British Cellulose and Chemical Company's Works, two of which were attended with fatal consequences, was told at an inquest at Derby on Monday on Arthur Dewdeney, engineer superintendent. The evidence showed that the Government during the war started a new process at the factory for the manufacture of acetic acid. Despite precautions, copper acetylide accumulated in the plant, and exploded, the actual cause being undetermined. The company undertook to adopt further safeguards, and the jury exonerated the works' chemists from blame.

BELGIAN PROHIBITION ON WHITE PHOSPHORUS MATCHES.—The Board of Trade are in receipt, through the Foreign Office, of copy of a Belgian Law, dated August 30, prohibiting the manufacture, importation, sale, and holding for sale, of matches containing white phosphorus. The Law authorises the Belgian Government to adhere to the International Convention regarding the Prohibition of the Use of White Phosphorus in Match Manufacture, signed at Berne on September 26, 1906. The provisions of the Law are to become effective six months after the date of publication, except as regards the prohibition relative to the sale and offering for sale of white phosphorus matches, which is not to become operative until twelve months after publication.

ALLEGED NEW MOTOR FUEL.—The Nottingham correspondent of the *Times* reports tests on Saturday last with a new motor fuel, the invention of a South American named Andrade. The test took place in the grounds of Alderman Ball, who has entered into a provisional arrangement with the inventor to secure the European rights. Mr. Ball states that a car travelled over thirty miles on one gallon, and that if Andrade's assertions are true a gallon can be manufactured for five-pence. The *Times* is informed that the inventor has been in this country for several weeks. Experiments have taken place in the presence of an experienced motor expert. It is stated that the inventor claims that by mixing certain chemicals with pure water a liquid is produced capable of providing motive power. Chemicals are introduced in the form of powders, and minor experiments carried out are reported to have proved very encouraging.

DUTY-FREE ALCOHOL IN BELGIUM.—In virtue of a Belgian Royal Decree of June 15, 1913, total exemption from excise duty was accorded in respect of alcohol destined for the manufacture of acetic or sulphuric ether, artificial silk, pure resin (for sale), and of alcohol employed to produce motive power; and partial exemption was accorded in respect of alcohol used for certain other specified industrial purposes. The excise duty then existing was 200 francs per hectolitre of alcohol of 50° Gay-Lussac at 15° C.; and the partial exemptions referred to were at the rates of 164, 110, and 190 francs per hectolitre, according to the use to which the alcohol was put. The excise duty having now been raised to 800 francs per hectolitre, the decree of June 15, 1913, has been superseded by a decree of September 4, 1919, which, however, only differs from the earlier decree in that the partial exemptions are now at the rates of 764, 770, and 790 francs per hectolitre respectively.

EMPIRE SUGAR RESEARCH.—The formation is announced of the British Empire Sugar Research Association with the object of establishing, in co-operation with the Government Department of Scientific and Industrial Research, an Empire scheme for the scientific investigation, either by its own officers or by universities, technical schools, and other institutions, of the problems arising in the sugar industry, and to encourage and improve the technical education of persons who are or may be engaged in the industry. The scope of the work to be done by the Association will include the investigation of problems arising in all branches of the sugar industry, including the improvement of the sugar-cane and sugar-beet, the methods of extracting the sweetening matter, the processes of refining, and the best methods for the use of sugar employed by manufacturers using sugar as one of their raw materials, as well as the discovery of the best uses of the after-products of both factory and refinery.

ELECTRIC RESISTANCE HEAT-TREATING FURNACE.—Two forms of a new type of electric resistance furnace have been developed by the General Electric Co., U.S.A., viz., a high-temperature (1,000° C.) furnace used in tempering and hardening gun forgings, and a low-temperature furnace (up to 510° C.) used for shrinking jackets on a variety of cores. According to the *Technical Review*, the furnace is built in units which may be fitted above one another to give a greater depth of heating surface. Each unit of the low-temperature furnace consists of a cylindrical casing with top and bottom castings and a heating unit of calorite ribbon mounted on, but insulated from, a cast-iron supporting plate. A one-section furnace is usually provided with automatic control. The construction of the vertical high temperature furnace involves the use of a heavy calorite ribbon supported on insulators embedded in the furnace wall of refractory bricks, so as to eliminate the inherent weakness of metal supports at high temperatures. Each section is controlled independently and automatically. The advantages claimed for this type of furnace include minimum temperature variation, uniform and maximum rate of heating, and the elimination of scale due to oxidation.

ACTION OF MURIATIC ACID ON MANILA ROPE.—At the instigation of the National Safety Council, an investigation has been undertaken by the U.S. Bureau of Standards to determine the action of muriatic acid on manila rope. The effect of this acid or its fumes on rope of this kind is a great menace, as the acid weakens the rope seriously without any superficial trace of the action being noticeable to the eye. When rope is exposed to this acid—as, for instance, when it is used in blocks and falls of swinging staging when washing down brickwork, etc.—many serious accidents have resulted, some of which have been fatal, owing to the fact that the rope has been weakened through contact with this acid or its fumes. The only practical remedy suggested is that of treatment of manila rope before using with some acid-resisting compound. An attempt will be made in this investigation to determine by testing the actual effect of the acid, and ascertain if the deterioration can be remedied by impregnating the rope with a certain compound which the National Safety Council advances as having been effective in protecting machinery and equipment from acid corrosion.

OBITUARY.—The *Times* announces the death of Mr. John Charles Umney, F.C.R., a leading authority on drugs, medicinal chemicals, and essential oils, which occurred on Thursday of last week at Berea Court, Yapton, Arundel. Mr. Umney, who was born in 1868, had for many years taken a leading part in the standardisation of these articles, and was largely responsible for the standards for medicines laid down by the Local Government Board, Ireland. He was a member of the Pharmaceutical Committee of Reference for the British Pharmacopœia. He was founder and editor of the *Perfumery and Essential Oil Record*, through which journal he stimulated aromatic plant cultivation and oil distilling in many parts of the world. His numerous publications included "Essential Oils in Relation to the British Pharmacopœia and Trade." He was a past president of the British Pharmaceutical Conference and of the Wholesale Drug Club. He had done valuable service as chairman of the Chemical Trade Section and the Toilet Soap Section of the London Chamber of Commerce. He had also been chairman of the Proprietary Articles Section of the Chamber and chairman of the Proprietary Articles Trade Association. In 1912 he gave important evidence before the Select Committee of the House of Commons on Patent and Proprietary Medicines.—Mr. Hugh S. Walker, a member of the firm of W. G. Walker and Sons, chemical manufacturers and tar distillers, Hawkhill Chemical Works, Ayr, died last week.

CORRESPONDENCE.

* * * We do not hold ourselves responsible for the opinions expressed by our correspondents.

The British Chemical Trade Association.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—If your correspondent "Dealer" (in your issue of October 11) has the courage to abandon his cloak of anonymity, and will apply to this office, I shall be very pleased to show him a list of members and also satisfy him that the Board of Trade recognises us as the Chemical Merchants' Association.

Our membership roll contains some of the most respected names in the trade—to use "Dealer's" own expression, "recognised dealers in chemicals before the war,"—and our organisation welcomes the fullest inquiry from respectable and responsible parties.—Yours, etc.,

THE BRITISH CHEMICAL TRADE ASSOCIATION.

O. F. C. BROMFIELD,

Assistant Secretary.

80, Fenchurch Street, London, E.C.3.
October 14, 1919.

COMING EVENTS.

Institution of Petroleum Technologists.—Meeting, Tuesday, October 21, at 5.30 p.m., at the House of the Royal Society of Arts, John Street, Adelphi, W.C. 2. Paper: "Some Laboratory Tests on Mineral Oils," by Arnold Philip. B.Sc., A.R.S.M., F.I.C.

College of Technology, Manchester.—Tuesday, October 21, at 4.30 p.m. Lecture by Mr. J. Allan on "Site, Layout, and Construction of Chemical Works."

Society of Chemical Industry, Birmingham and Midland Section.—Meeting, University Buildings, Edmund Street, Birmingham, on Thursday, October 23. Paper by Mr. E. C. Rossiter, on "Potash Production."

REPORTS OF COMPANIES.

American Cyanamid Company.

The report for the year to June 30 last states that operation of the cyanamide plant at Niagara Falls has been at full capacity for the entire year, and a new record has been attained from the standpoint of material produced. Improvements now being installed at this plant will give still larger production and a greater manufacturing efficiency. Under the contract between the company and the United States Government practically the entire output of cyanamide was delivered in the form of aqua ammonia. Coincident with the signing of the armistice, operations under this contract were suspended. The manufacture of ammo-phos and sulphate of ammonia was promptly resumed at the New Jersey plant, and a foreign market immediately developed for all material produced. The location of the ammo-phos works in New York Harbour has proved advantageous both in the manufacture and distribution of ammo-phos and has consistently obtained for the company a premium export price for sulphate of ammonia. Operations of the phosphate mines were on the basis of full capacity until the beginning of last May when all work was suspended by a walk out of employees. The strike was general throughout the district, and affected all mining companies. Operations have since been resumed and are now approaching normal capacity. This company has acquired membership in the Florida Pebble Phosphate Export Association, organised by the leading pebble phosphate mining companies, under the so-called "Webb Act" for the promotion of foreign trade. The outlook is promising for a profitable export business in phosphate rock during the next two years. Further improvements have been made in the manufacture of aero brand cyanide from cyanamide, and the market for this product has widened during the year. The work of Air Nitrates Corporation, a subsidiary, formed to act as agent of the United States in the construction and operation of plants for the manufacture of ammonium nitrate by way of the cyanamide processes, was vigorously prosecuted. The plant at Muscle Shoals, on the Tennessee River, for which ground was broken on February 16, 1918, began manufacture on October 26 following. In quality of product and efficiency of operation, the results obtained at this plant were from the start most gratifying, and are the more remarkable in view of the rapidity of its construction. Manufacture at Muscle Shoals and the construction of two additional plants—one at Toledo, Ohio, and the other near Cincinnati, Ohio—both well advanced, were discontinued by order of the Government soon after the signing of the Armistice. The total sales for the fiscal year have amounted to \$6,205,386, as compared with a corresponding total of \$6,194,668 for the preceding fiscal year. Active trade relations were suspended in the summer of 1917, and until December, 1918, because of the Government contracts in hand during that period, but this company has in hand as at June 30, 1919, contracts for delivery prior to June 30, 1920, of various products estimated to have a sales value of \$2,559,186.

Ducktown Sulphur, Copper, and Iron Company, Ltd.

At the annual meeting held in London on Thursday (October 9), Mr. J. G. Gordon, chairman, said: While the development work at the mines has been satisfactory, so far as a largely increased tonnage is concerned, the assays show that the copper content of these large ore bodies is considerably lower than the ore we have hitherto treated. We therefore came to the conclusion that we would have to considerably modify our present process for treating the ore, and, after careful experiments decided that a process on which we have been experimenting for some years past was well adapted for this purpose. We have taken all the necessary preliminary steps for installing such a plant, which should during the year 1920 enable us to treat about 800 tons of ore per day on a seven-day week. This will be nearly double the output we have hitherto made, and will largely reduce all the overhead costs. Careful calculations made on the basis of our long experience in mining and smelting, and on the experiments I have already alluded to, carried on for some years, and our knowledge of these processes carried out elsewhere, go to show that even with the lower copper content, the profits from the copper alone will be somewhat greater per ton of ore than those we have hitherto obtained. The general opinion of copper people in the United States when I left was that, owing to present conditions of labour and essential materials, while in pre-war days the normal price of copper was regarded as about 14 cents per pound of copper, 20 cents per pound

of copper is now regarded as the equivalent of that price; therefore we should now, with 20-cent copper, make a larger profit per ton of ore treated than we could formerly calculate on at 14 cents per pound of copper, and added to this, as I have already mentioned, we shall be treating approximately double the quantity, so that the profits in future should be materially increased. Since 1910, we have made a small profit out of the sulphur contained in the ore, which was converted into sulphuric acid. This profit was not taken into account in the calculations I have just alluded to, but here, also, we are hopeful that by improved methods, and especially by the better co-ordination of the smelting and acid plants, decidedly better results will be obtained in the future. A further encouraging feature, in my opinion, is that by the new process a considerable amount of the iron contained in the ore will be recovered in such a state that it can be made into a saleable product. Hitherto all the iron in the ore has gone into the slag, and could only be so disposed of, which added little, if anything, to our revenues.

The reports and accounts were unanimously adopted.

Pena Copper Mines, Ltd

The report for the year to December 31 last states that the total amount spent on new railway and rolling stock up to that date is £193,656. The total amount of depreciation written off to end of 1918 is £27,689, leaving a balance of £165,967. The value of buildings, fixed plant, old branch railway, etc., after allowing for depreciation, stands at £52,156. The quantity of overburden removed during the year was 21,349 cubic metres, as compared with 30,320 cubic metres in the previous year. The amount at the debit of this account is now £72,950. The total output of ore from the mine was 91,827 tons, against 160,121 tons in 1917. The output was dealt with as follows: Ore added to the heaps for leaching, 49,493; ore for export, 42,334 tons. The total value of the mineral stocks was £124,082, as against £107,010 at the beginning of the year. The production of copper precipitate totalled 554 tons, against 587 tons in 1917. The average price of best selected copper was £126. 5s. in 1918, as against £137. 14s. 11d. in 1917. The shipments of ore totalled 72,023 tons, against 145,120 in 1917. The profit on sales of produce, plus interest, registration fees, etc., after charging £7,278. for depreciation, amounted to £20,926. London administration expenses, income-tax, and French dues and charges were £17,495, and interest upon loans, etc., £10,385.—together, £27,880. Deducting the gross profit above mentioned, £20,926, there is a loss on the year's working of £6,954.; to this must be added amounts advanced to the Cala Railway Co., now written off, £12,303., making a total loss for the year of £19,257. Deducting this from the balance brought in from last year—viz., £83,038—there remains a balance to be carried forward of £63,781.

A. and F. Pears, Ltd.

The net profits for the year ended June 30 were £103,896., and £16,406. was brought forward. A dividend of 20 per cent. is proposed, adding £5,000. to the reserve, and carrying forward £14,902. The company's net profits were £91,438. for 1917-18, £90,738. for 1916-17, £90,427. for 1915-16, and £78,812. for 1914-15, and the proportions were in all respects similar to those for the past year, except that £10,000. was reserved in 1915, when £30,003. was carried over.

Wilkie and Soames, Ltd.

The report for the year to June 28 last states that the net profit, after providing for depreciation, amounts to £24,181., and £19,464. was brought in, making 30 per cent. for the year, carrying forward £21,145., subject to excess profits duty (if any).

British Platinum and Gold Corporation, Ltd.

The following circular has been issued to the shareholders. "I am instructed to inform you that a cablegram to the following effect has been received from our managing director, Mr. Thos. J. Ive, who has recently visited this Corporation's properties in Columbia:—I have entered into an agreement with Messrs. Pugliese, Figerio and Mayolo by which the British Platinum and Gold Corporation secures control of all their platinum and gold bearing properties in the Choco district, on very favourable terms to the British Platinum and Gold Corporation, Limited. One valuable property is now ready for a dredger. This property is estimated to contain 5,000,000 cubic yards, having a value of 2s. per cubic yard. This value is calculated on a basis of 12lb. per oz. crude plati-

num, being the same basis on which the British Platinum and Gold Corporation, Limited, based their calculations for their own properties. Full instructions have been given by me to the consulting engineers of the British Platinum and Gold Corporation, Limited (Messrs. Inder, Henderson and Dixon), for the construction of a dredger as early as possible. The terms of the agreement entered into with Messrs. Pugliese, Frigerio and Mayolo involve no payment in cash, but provide for a division of profits after paying working expenses and providing the necessary funds in repayment of cost of dredger and equipment. Mr. Mayolo, of Messrs. Pugliese, Frigerio and Mayolo, joins the board of directors of the British Platinum and Gold Corporation, Ltd."

DIVIDENDS.

BORAX CONSOLIDATED, LTD.—A dividend of 6 per cent. per annum, less tax, on preferred ordinary in respect of half-year ending September 30, 1919.

VIRGINIA CAROLINA CHEMICAL COMPANY.—A quarterly dividend of 2 per cent. per annum (2 dols. per share) on preferred, and dividend of 1 dol. per share (1 p.c.), on common.

NEW COMPANIES.

British Ulco Company, Ltd.—Capital £40,000., £1. shares. Agreement with United Lead Company, the Broken Hill Associated Smelters' Production, Ltd., Messrs. Locke, Lancaster and W. W. and R. Johnson and Sons, Ltd., and Cookson and Co., Ltd. Buyers, sellers, and manufacturers of and dealers in ores, minerals, and mineral substances of all kinds, including alloys. Solicitors: Broad and Co., 1, Great Winchester Street, E.C.

Federation of Bone Users and Allied Trades, Ltd.—Registered September 17 as a company limited by guarantee, with 200 members, each liable for £5. in the event of winding up. Objects: To promote, develop, and protect the interests of the glue, bone fertilisers, fats, bone products, etc., trades. The management is vested in a general council, the first members of which are R. Duncalfe, A. Macdonald, H. J. Cotes, G. Jones, J. S. Hegarty, E. H. Quibell, W. S. Corder, J. W. Stevens, E. R. Brown, and T. Somerville. Solicitors: Coward and Hawksley, Sons and Chance, 30, Mincing Lane, E.C.

Martin's Oilfields of Madagascar (Parent) Company, Ltd.—Capital £10,000., £1. shares. Secretary: E. S. G. Greene, Clifford Chambers, 10, New Bond Street, W.

South Africa Carbide and By-products Company, Ltd.—Capital £307,500., in 300,000 shares of £1. each and 150,000 shares of 1s. each. Registered office: 2, Broad Street Buildings, E.C.

Archibald Stevenson and Co., Ltd.—Private company. Capital £30,000., £1. shares. Manufacturers of soap, lubricating oils, etc. Office: 23, Philpot Lane, E.C.

Charles Knott, Ltd.—Private company. Capital £3,000., £1. shares. Importers and exporters of general produce and raw materials of all kinds, dealers in chemicals, etc. Registered office: 44, Bedford Row, W.C. 1.

Derby Fertilisers, Ltd.—Private company. Manufacturing chemists, manufacturers of, agents for, and dealers in chemical and other manures, fertilisers, etc. Registered office: 3, Market Place, Derby.

Donald Campbell and Co., Ltd.—Private company. Capital £500,000., £1. shares (499,700 ordinary and 300 employees'). Wax and oil merchants, dealers in Eastern and general produce, etc. Registered office: 10, St. Mary Axe, E.C.

Hirst and Co., Ltd.—Private company. Capital £1,000., £1. shares (700 preference). Soap manufacturers, pharmaceutical, manufacturing, and general chemists and druggists, etc. Registered office: The Soap Works, Dronfield, Derby.

Midland Metallurgical, Ltd.—Private company. Capital £1,000., £1. shares. Manufacturers, importers, and exporters of and dealers in metals, ores, etc. Office: Norfolk House, 36, Cannon Street, Birmingham.

Shotter and Dare-Mordle, Ltd.—Private company. Capital £50,000., £1. shares. Object: To acquire a freehold factory at Perry Barr, Birmingham, with certain starch manufacturers' stock-in-trade and plant and trade-marks, an invention of a starch drying machine, etc., belonging to F. B. Shotter and L. Dare-Mordle, etc. Registered office: Wellhead Works, Aldridge Road, Perry Barr, Birmingham.

Premier Oil Company, Ltd.—Capital £3,750,000., 15s. shares. Office: 2, Gresham Buildings, Basinghall Street, E.C.

Cement Developments, Ltd.—Private company. Capital £1,000., £1. shares. Office: 1, Broad Street Place, E.C.

John Wheeldon and Co., Ltd.—Private company. Capital £5,000., £1. shares. Objects: To take over the business of oil refiners, tallow melters, etc., carried on by Lillie Wheeldon at 90, Eyre Lane, Sheffield, as "John Wheeldon and Co." and "John Thomas and Co." Registered office: 90, Eyre Lane, Sheffield.

Metal Deposition, Ltd.—Private company. Capital £5,000., in 4,000 preference shares of £1. and 20,000 deferred ordinary shares of 1s. each. Object: To acquire, exploit, and turn to account any process for the deposition of metal on aluminium or other substances, etc. Registered office: 52, Charing Cross, Whitehall, S.W. 1.

Richards Turpin (Minerals), Ltd.—Private company. Capital £25,000., £1. shares. Objects: To take over the business of merchants, shipowners, and ore importers carried on at Gloucester House, Swansea, and elsewhere as "William Turpin and Co." Registered office: "Gloucester House," Gloucester Place, Swansea.

J. W. Kitson and Co., Ltd.—Private company. Capital £17,500., in 16,000 10 per cent. preference shares of £1. each and 30,000 ordinary shares of 1s. each. Boiler and steam-pipe coverers and manufacturers of Kitson's Eureka non-conducting compositions. Registered office: 21, Brunswick Street, Blackwall, Poplar, E.

Vulcan Trading Corporation, Ltd.—Private company. Capital £1,010., in 10 preference shares of £100. each and 10 ordinary shares of £1. each. Object: To carry on the business of manufacturers of and dealers in iron, steel, metals, machinery, chemicals, materials and goods of all kinds, shipowners, brokers, importers, exporters, and producers of raw and manufactured products, metals, machinery, minerals, chemicals, manures, oils, fats, etc. Registered office: 35, New Broad Street, E.C.

Walter Everitt, Ltd.—Private company. Capital £10,000., £1. shares. Object: To take over the business of an analyst and manufacturing chemist formerly carried on by W. Everitt and Co., Ltd., at Norwood Wharf, Southall. Solicitors: J. B. and F. Purchase, 14, Regent Street, S.W. 1.

Fine Chemicals, Ltd.—Private company. Capital £25,000., £1. shares (15,000 ordinary and 10,000 7 per cent. cumulative preference). Object: To take over the business of wholesale and retail chemists carried on by the Apothecaries Hall, 40, Mary Street, Dublin. Registered office: 40, Mary Street, Dublin.

Goonvean China Clay and Stone Company, Ltd.—Private company. Capital £150,000., £1. shares. Registered office: 3, Bodmin Road, St. Austell, Cornwall.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

Prospects are brighter this week, though there is not yet a full return to normal conditions. There is, however, an under-current of uneasiness on account of the diminishing demand for iron. There should be no decrease in output for ten or twelve weeks yet, production to the end of the year having been sold long ago; but there is not now much new business being booked, and there is not a strong anticipation of trade reviving until the steelworks can secure a larger share of Continental rail orders. At present the 380 by-product coke ovens in this district are not working at more than half their capacity, and as a result more small coal has been shipped to Ireland than at any time since August of 1914. With twenty-five furnaces in draught between Workington and Carnforth, however, a substantial increase in the production of coke will be necessary. East Coast coke supplies have already risen, the consumption between Millom and Carnforth having mounted this week to 12,000 tons, and in West Cumberland to 8,000 tons. By-product output has of course suffered a reduction. There is still a very weak demand for acids, and as a result a portion of the plant of the chemical works on this coast is idle. Benzole is fully absorbed. There is a brisk inquiry for sulphate of ammonia for home users, and pitch is fairly strong. Cresote is duller.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Nitrate of Soda.—Last month's shipments from Chili were again on a very moderate scale—in fact, smaller than those in August, the total being in round figures 44,000 tons, of which 20,000 tons went to Europe and 24,000 tons to the United States and other parts. There was also a further slight falling-off in the production at 103,000 tons, but an increase of 59,000 tons in the stocks on the Coast to 1,712,000 tons; this quantity is more than double that on hand a twelvemonth ago, and compares with 754,000 tons on October 1, 1913, before the dislocation of the industry by the European War. There were then 171,000 tons "loading" and 340,000 tons "afloat" for Europe, whereas the corresponding figures were only 28,000 and 30,000 tons on the 1st inst., the present European stocks being as well unusually small. On the other hand, those in Chili, it will be seen, exceed by about one million tons the quantity available in normal times, and the disposal of this surplus prevents a serious problem in view of the scarcity of tonnage. As regards the sale itself of the nitrate, a good beginning has been made, the Producers' Association having placed at 9s. 4d. for November and 9s. 6d. for January-February delivery a further 50,000 tons, making 800,000 tons since the middle of September. Not only this, but offers for other large quantities on similar terms are said to have been refused, and a further advance in the "fixed" prices is on the tapis, although second-hand parcels are freely offered at less money. The buyers of all this nitrate have presumably secured the necessary tonnage, but it must have been at rates rendering the Chilean fertiliser an *article de base* when 250s. per ton freight is paid for a steamer carrying 12,000 tons November-December loading to the Continent. The British farmer so far takes no interest in nitrate of soda, but holders of nitrate shares are once more hoist into the seventh heaven!

Sulphate of Ammonia.—Trading in this fertiliser shows a fair undertone, but is not particularly active. The home price is rising slightly month by month in accordance with the control arrangements. This, apparently, offends some consumers, although it can easily be shown that they would have to pay a good deal more per ton in a free and unrestricted market. It is believed that the American producers expect to figure larger and larger in the outside markets formerly supplied from this country, but all that remains to be seen. News from the Pacific Coast districts of the United States says that sulphate of ammonia for later delivery is being sold at a reduced price, but spot stocks command a premium owing to the scarcity of local supplies. On the coast the delivered price is believed to have dropped in sympathy with nitrates, but it is doubted there whether it will go any lower. Autumn business has pretty generally been adjusted on a basis of the new nitrate and sulphate of ammonia costs, and this would seem to point to a certain expected stability in the market quotations. That there will be a popular demand for sulphate of ammonia in the far West seems assured. Effective publicity work has created a special interest in this fertiliser the last few years. At the 58th annual convention of the American Chemical Society many interesting papers were read in the Fertiliser Division. In one of these the writer found that the tendency of ammonium sulphate to cake, even after drying and screening, was due to pyridine sulphate, and was overcome by treating the dry ammonium sulphate with ammonia gas, thus setting free the pyridine and permitting its removal. The exports of sulphate of ammonia from Great Britain for the first nine months of this year are returned at 56,318 tons, as against only 12,370 tons in the corresponding nine months of last year and 51,213 tons in the corresponding period of 1917. The biggest buyer this year has been Japan, with 18,410 tons, after which comes France with 10,558 tons. The third place is occupied by the Dutch East Indies with 7,938 tons, and the fourth by Spain and the Canary Islands with 4,820 tons.

Fish Guano.—Developments are promised in the utilisation of fish wastes in this country. We read that one of the largest plants on the East Coast is now doubling its capacity in order to raise its output from 20 tons to 40 tons per 24 hours, or somewhere about 12,000 tons of fish guano per annum. With the new process which is now being used the ammonia value is increased from $7\frac{1}{4}$ per cent. to 12 per cent., and it is pointed out that every rise of 1 per cent. in the ammonia content is worth about twelve times as much as the improvement of the phosphatic content to a corresponding degree.

Nitrate of Lime.—Despite its widely recognised efficiency, nitrate of lime in pre-war days was used only in very limited quantities as a fertiliser in this country. The handicap from which it suffered was its proportion of dust, which accentuated its natural tendency to absorb moisture from the air and become wet and sticky before the operation of sowing could be completed. It is interesting to note, therefore, that the manufacturers have now succeeded in granulating nitrate of lime and evolving practically a dust-free product, which can be conveniently and efficiently spread either by hand or machine. The removal of the sowing difficulty must be regarded as an important advance towards the wider appreciation and adoption in this country of this particular form of synthetic nitrate for fertilising purposes.

Bone Meals, Blood, Etc.—Bone meals and allied substances are still in very short supply. Prices are firm, but at the moment there is little doing on agricultural account. In River Plate tankage there is practically nothing offering, and the nominal value is 30s. per unit of ammonia. The same remark applies to dried blood, with very little offered, the nominal price being 30s. to 32s. 6d. At times a good inquiry is reported to have been manifested for meat meal with values as above.

German Fertiliser Difficulties.—The *Frankfurter Zeitung* has news from the Central Society for the Supply of Agricultural Requirements that the situation in respect to supplies of fertiliser is a very poor one. For the present harvest, in consequence of the scarcity of coal, which prevents the nitrogen-producing factories from reaching their possible production, the quantities of available nitrates are remarkably reduced. Superphosphate also is only to be had in very small quantities. The greater portion of the goods produced is delivered in the form of a mixture of ammonia-superphosphate. With regard to the supply of potash salts, the delivery facilities have considerably worsened. Of kainit and chloride of potash, some of the orders given in the first half of last year are still unexecuted. The Potash Syndicate does not grant any preferences. It is not yet decided whether, and in what respect, basic slag will be available for this year. Generally, a very great scarcity is in view for the whole series of fertilisers for the beginning of the coming year.

Alsatian Potash.—The deliveries of Alsatian potash salts in the United Kingdom during August and September were 2,576 tons. Shipments for the week ending October 11 were 1,928 tons of sylvinit, 14 per cent., (French kainit). Current quotations for Alsatian potash salts are as follows: Sylvinit, 14 per cent., £7. per ton; sylvinit, 20 per cent., £8. 7s. 6d. per ton; and muriate of potash, 80 per cent., £19. 7s. 6d. per ton.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

It was not until the commencement of the week that the whole of the tinplate mills were fully operating, owing to the difficulty of transport of coal and steel bars. The outputs show a gradual increase over those of a few months ago, but they are still below the demand for all kinds of plates. The largest cargo ever loaded at Swansea left that port for Japan with 10,000 tons of tinplates and galvanised sheets.

The patent-fuel trade was not so seriously affected by the railway strike, and many of the factories were enabled to carry on without interruption owing to the stocks of small coal on hand. Messrs. T. P. Rose Richards and Co. have acquired a site from the Swansea Harbour Commissioners for the erection of a new fuel factory, and a lease for 99 years has been agreed to.

As the demand for coke keeps very active, the by-product ovens are yielding good supplies of ammonia, benzole, etc. A few more ovens are now in operation, and with the commencement of next year it is anticipated that many more will be ready. As regards sulphate of ammonia, there is a steady trade, and as stocks are low there is no indication that any vigorous export business will be seen during the next three months. Home inquiries are numerous, but as yet no volume of trade is being booked, farmers withholding their orders, but manufacturers in South Wales are confident that there will be a very active season for this fertiliser.

There is much activity in the basic slag trade, but the production of this manure has not increased much since the cessation of hostilities. Stocks are very low; in fact in some instances there is a difficulty in executing orders.

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS.

THE following returns, which are taken from the import statistics of the United Kingdom, give the amount and value of chemicals and allied products imported during the month ending Sept. 30th, 1919, as compared with Sept., 1918.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

October 6th to 11th (inclusive).

Solidifying Kerosene. Akker, J. J. 24,665.
Drying Liquids. Akkerman, J. H. 24,704.
Delivering Pulverous and Granulated Materials. Aktiebolaget Svensk Färgämnesindustri. 24,634.
Furnaces or Retorts for Subjecting Ores, etc., to Action of Gases, etc. Balfour, I. H.; Bray, S. W.; and British Oxygen Co. 24,721.
Para-cymene. British and Foreign Chemical Producers, Ltd. (Rheinische Kampferfabrik-Ges.). 24,331 and 24,388.
Disazo-colouring Matters. Brotherton and Co.; Merriman, R. W.; and Mersey Chemical Works. 24,870.
Sedimentation Apparatus. Dorr Co. 24,936.
Roasting Zinc Oxides Preparatory to Leaching. Electrolytic Zinc Co. 24,744.
Cracking Hydrocarbon Oils. Holmes, R. C.; and Manley, F. T. 24,615.
Separators for Granular and Pulverulent Materials, Matter in Suspension, etc. Hooke, H. 24,708.
Sheep and Cattle Dips and Insecticides. Howles, F.; and McDougall, I. 24,915.
Coating-Compositions or Paints. Isaacs, M. R. 24,606.
Solder for Aluminium, etc. Iversen, R. 24,410.
Purification, etc., of Liquids, etc. Llewellyn, I. P.; and Spence and Sons, P. 24,688.
Aluminous Compounds. Llewellyn, I. P.; Spence, H.; and Spence and Sons, P. 24,875.
Solvents for Acetylene, etc. Marks, E. C. R. (Prest-o-lite Co.). 24,848.
Resin-like Bodies. Melamid, M. 24,916 and 24,917.
Machine for Mixing Paint, etc. Mellor, S. C.; Niehuus, R. H.; and Shearer, J. A. 24,501.
Viscose from Cellulose. Müller, R. 24,737.
Deodoriser. Newth, W. H. D. 24,572.
Detergent Composition. Newth, W. H. D. 24,594.
Automatically Indicating Depth of Liquids in Tanks, etc. Nicholson, A. I. 24,687.
Explosives. Nobel's Explosives Co.; Nolan, T. J.; Rintoul, W.; and Stickland, O. W. 24,841.
Sulphuric Acid. Parrish, P.; and South Metropolitan Gas Co. 24,386.
Purifying Liquids by Electricity. Perrett, I. G.; and Wilson, J. 24,502.
Vulcanisation of Rubber. Stevens, H. P. 24,333.
Liquid Fuel. U.S. Industrial Alcohol Co. 24,852.
Thorium Compounds. Wade, H. (Lindsay Light Co.). 24,925.
Oxide of Zinc. Walkey, W. R. 24,426.
Evaporating or Concentrating Apparatus. Webb, E. T. 24,898.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 6d. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.

1916.

Treatment of Hydrocarbons. Forwood, G. F.; and Taplay, J. G. 17,869. **133,059**

1917.

Extracting Oils, Fats, and Other Greases from Garbage, House Offals, and Other Refuse Containing also Water. Dehn, F. B. (Cobwell Corporation). 11,252. **133,075**
Controlling and Regulating Devices for Gaseous Fluids. Parade, J. C. J. de Lastang. 16,305. **133,084**

1918.

Producing Substantially Pure Cyanogen Compounds. Nitrogen Corporation. 3,415. **133,095**
Carbide. Reid, J. H. 4,445 and 4,447. **133,098** and **133,100**
Electrical Furnaces. Reid, J. H. 4,446. **133,099**
Preparation of Crude Materials for Manufacture of Calcium Carbide. Slocum, F. L. 4,448 and 4,450. **133,101** and **133,103**
Preparation of Crude Materials for the Manufacture of Metal Carbides. Slocum, F. L. 4,449. **133,102**
Fixation of Nitrogen. Slocum, F. L. 4,451. **133,104**
Cyanogen Compounds and Ammonia. Slocum, F. L. 4,452. **133,105**

Treating Material with Gas or Vapour. Stutz, C. C. 4,456. **133,106**
N-aryl-thio-morpholines. Robinson, R.; Kay, F. W.; and British Dyes, Ltd. 10,503. **133,108**
Recovery of Gaseous Products from Plants for the Destructive Distillation of Organic Materials. Bury, E.; Ollander, O.; and Bury, A. F. 16,121. **133,159**
Coating or Covering the Surface or Surfaces of Metal with Lead or Its Alloys. Thompson, R. W.; and Morrison, J. 16,695. **133,179**

Vitamine Preparations. Inray, O. (Soc. of Chemical Industry in Basl.). 16,830. **133,183**
Cement. Bärnhielm, B. 17,717. **121,728**
Treatment of Liquids with Gases. Magrath, H. J. 20,270. **133,217**

Recovery of Proteids from the Waste Liquors of the Hide-treating Art. Dorr Co. 20,284. **123,974**

1919

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Nitrocellulose. W. B. Thomson, W. D. Severn, and G. Twy-cross, Cape Town. British Patent, 130,665, of 1918.

The wood of the baobab tree is used as the raw material for making nitrocellulose. The wood is disintegrated, boiled in weak caustic-soda solution, and washed; it is then treated with dilute hydrochloric acid in a pulping-apparatus until the fibre is substantially separated into single strands, and then washed, dried, and nitrated in the usual manner.

Cyanogen Compounds. F. L. Slocum, Pittsburg, U.S.A. British Patent, 130,680, of 1918.

Apparatus for treating materials with gases, particularly for obtaining nitrogen compounds from carbides and ammonia from these compounds, comprises a series of furnace-chambers 2 each having end doors 3 and a top 4 with an outlet 5 for the gases passing through a trap 6. Extending from

one end of the heating-chamber is a platform 9 for the charging-rack. The rack consists of a frame 10 comprising up-rights 11, side-pieces 12, and cross-pieces. The rack is provided with rollers 16 and carries perforated trays 17, which may be provided with a lining of wire mesh. The rack is moved into and out of the heating-chamber by mechanically operated means.

Luminous Paints. G. A. H. Muller and J. Macfarlane, Montreal, Canada. British Patent, 130,885, of 1919.

A luminous paint is manufactured by heating together sublimed sulphur and carbonates of strontium, calcium, and magnesium. The strontium carbonate is preferably the predominant constituent of the carbonates, the proportions in one example described being sulphur 26 parts, strontium carbonate 19 parts, calcium carbonate 6 parts, and magnesium carbonate 1 part. The mixture is furnace in a crucible at a temperature of about 1500° F., then ground, and made up into a liquid paint by mixing with a colourless varnish prepared from mastic and similar gums with turpentine, spirit, or drying oils.

Vulcanisation of Rubber. North British Company, Edinburgh. British Patent, 130,857, of 1918.

A previously prepared compound of sulphur and a nitrogen-containing body is used for vulcanising. The compound of the sulphur and nitrogenous substance may be prepared in the presence of an aromatic amine such as aniline. Examples of nitrogenous bodies are substituted thio-ureas such as thio-carbanilide, methylene bases such as methylene aniline, para-nitroso compounds such as para-nitro-dimethyl-aniline, and guanidine derivatives such as tri-phenol guanidine, cyanides, proteids and their decomposition, and hydrolysis products, including amino acids, animal glue, or gelatine. Sulphur may

be added to the sulphur compound. With the exception of a few of the compounds mentioned, the nitrogen-containing bodies contain the amino group or a substituted amino group.

Ammonia. E. B. Maxted, Highgate Road, Walsall, Staffordshire. British Patent, 130,063, of 1918.

Ammonia is produced synthetically by heating a gas mixture containing hydrogen and nitrogen to flame temperature under an elevated pressure—for example, 50 atmospheres—by partial combustion with air, oxygenated air, or oxygen in a pressure flame burning under such conditions that no free oxygen is present after combustion, the heating being followed by rapid cooling of the flame gases for the retention of the ammonia formed. The flame temperature must be at least $1,500^{\circ}\text{C}$. The residual gases after the removal of the ammonia may be re injected into the pressure flame. The process may be carried out in apparatus as shown in which the mixture containing hydrogen and nitrogen, and the oxygen, etc., are introduced, under pressure through inlets J, L and burnt in a combustion-chamber M, the flame gases being rapidly cooled and the ammonia absorbed by direct contact with water or acid contained in the vessel N and circulated by a pump P through a cooling-coil Q. In a modified

form of apparatus, the gases from the combustion-chamber are passed through a cooling-coil surrounded by running water, and are then led away to an absorber.

Sulphuric Acid Manufacture. K. B. Quinan, Somerset West, Cape Province, South Africa. British Patent, 130,712, of 1918.

In the process of preparing sulphuric acid involving the use of nitric oxide, reactions between liquids and gases are brought about by distributing the liquid over perforated horizontal diaphragms through which the gas is passed. The reactions are effected in a series of vessels through which liquid flows from an inlet 22, Fig. 3, to an outlet 23 over a perforated diaphragm 21, below which gas is supplied by a pipe 20*. The gas passes away by an outlet 20*. In a complete plant the gases produced by burning sulphur, pyrites,

etc., are passed through a dust-separator and a tower down which weak denitrified acid flows. The gases are passed in succession through a series of reaction vessels 19, 19^a . . . 19^h, Fig. 2, and are withdrawn by an exhaustor 39. Acid from the washing-tower is pumped through pipe 17, and supplied in

parallel to the three last reaction vessels 19^f, 19^g, 19^h, which discharge into a tank 32 to which nitric acid and water are added by pipe 45. The acid from the tank 32 is pumped into a tank 35, and supplied in parallel to the next vessels 19ⁱ, 19^j, 19^k, which discharge through coolers 25^c, 25^d, 25^e to a tank 29. The acid is supplied to the first vessels 19, 19^a, 19^b, and passes through coolers to a tank 26, and thence to the washing-tower.

Acetic Anhydride. H. Dreyfus, London. British Patent, 130,660, of 1918.

The production of acetic anhydride by the reaction of sulphur trioxide upon sodium acetate or other acetates, alone or diluted with acetic anhydride, is effected by using gaseous sulphur trioxide diluted with inert gases, such as the gaseous mixture produced in the contact process or manufacturing sulphur trioxide, and working at low temperatures (0 to 20°C or lower).

Removing Sulphur Compounds from Gases. E. K. Rideal and H. S. Taylor, London. British Patent, 130,654, of 1918.

Sulphur compounds contained in coal gas, water gas, producer gas, etc., are converted into sulphuretted hydrogen by passing the gas, mixed with a quantity of water vapour insufficient to produce reduction of the catalyst, over heated iron oxide mixed with one or more of the oxides of chromium, nickel, cobalt, cerium, thorium, zirconium, manganese, or molybdenum, which serve as promoters for the reaction. The catalyst is maintained at a temperature of 300° to 650°C . The sulphuretted hydrogen may be removed from the gas by known methods, such as absorption by iron oxide.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Acetaldehyde. Compagnie des Produits Chimiques d'Alais et de la Camargue, Paris. British Patent, 130,650. Convention date, January 12, 1917.

In the production of acetaldehyde by passing acetylene into acid solutions of mercury salts, the aldehyde is continuously removed from the liquid by applying a vacuum. Using the apparatus shown, acetylene is passed by a pipe B into the reaction liquid in a vessel A; the liquid passes by the pipe D to a receiver F in which a partial vacuum is maintained by a pump G; the vapour of aldehyde and steam pass off to the pump, while the liquid feed from aldehyde returns by a pipe H to the vessel A. The rise of the liquid in the pipe D may be assisted by a steam jacket K, by admitting air by a pipe L, or by other means.

Ammonium Chloride. L'Air Liquide Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude, Paris. British Patent, 130,365. Convention date, August 25, 1917.

Ammonium chloride is prepared by treating synthetic ammonia according to the ammonia-soda process, the carbon dioxide for the process being obtained in part from the water-gas used in making the hydrogen for the synthesis of the ammonia, and in part by calcining the sodium bicarbonate to produce sodium carbonate. To obtain the ammonium chloride free from bicarbonate so that it may be used as a manure, it is purified by fractional crystallisation, or the solution, after separation of the precipitated sodium bicarbonate is neutralised by acid before the ammonium chloride is crystallised out. The manufacture of the water-gas may be so conducted that the gas consists of hydrogen, carbon monoxide, and carbon dioxide, the carbon monoxide being in such proportion that it is sufficient, in conjunction with the waste hydrogen from the ammonia synthesis, to supply the power necessary

for the process. The hydrogen may be obtained from the water-gas by cooling and compressing the gas to liquify the carbon dioxide and then treating the cooled and compressed gas with a solvent as described in Specification 130,358 to extract the carbon monoxide. Alternatively, a water-gas consisting of carbon monoxide and hydrogen may be produced and then catalysed with steam to produce carbon dioxide and hydrogen.

Acetic Acid. Compagnie des Produits Chimiques d'Alais et de la Camargue, Paris. British Patent, 130,651. Convention date, March 6, 1917.

In the production of acetic acid by the oxidation of aldehyde vapour by air or oxygen in towers in the absence of a catalyst, accumulation of peracetic acid in the towers is prevented by providing a supplementary heating-chamber below the towers, into which the liquid acetic acid falls, carrying with it any peracetic acid present, which then decomposes. Using the apparatus shown, a current of aldehyde entering by a pipe A, and a current of oxygen or air entering by a pipe C mix in the vessel B, and pass to a decomposing-vessel E kept at about 100° C. by a steam-jacket F; the gaseous mixture then flows into an oxidation tower H packed with quartz, broken glass, etc., and provided with a water-jacket K; the liquid acetic acid formed, together with any undecomposed peracetic acid, drops into the vessel E, in which the peracetic acid decomposes. The gaseous mixture from the

tower H passes on to similar towers L, L¹, L², in which most of the remaining aldehyde is oxidised; the liquid products from these towers pass by the pipes, O, P, Q, S, B, D, and a liquid seal M, to the vessel E; the seal M is also steam-jacketed to prevent any accumulation of peracetic acid therein. The gases finally pass to a reflux condenser R any condensed aldehyde returning to the plant by pipe S, and the last traces of aldehyde are absorbed by acetic acid in a tower T, the solution flowing back to the plant by pipe V. A flask W through which the gases exhaust serves to indicate the rate of gas-flow. From the vessel E the acetic acid flows through a series of vessels X, Y, through which the entering current of air or oxygen bubbles to remove aldehyde, and the pure acetic acid flows off by a pipe Z.

Fertilisers. C. Rossi, Legnana, Italy. British Patent, 130,963. Convention date, August 9, 1918.

The potassium content of a rock such as leucite, volcanic ash, felspar, orthoclase, granite, and the like, is obtained by strongly heating the rock in a finely ground condition with calcium carbide in a stream of nitrogen. The potassium compound is volatilised, whilst the nitrogen is fixed by the calcium carbide as calcium cyanamide and by the rock forming a complex nitrogen-bearing compound. The nitrogenous residue, with or without the addition of the potassium compound, can be used as a fertiliser. Lime may be added to the reacting bodies in addition to that present in the calcium carbide; and carbon may be added in addition to that produced in the formation of calcium cyanamide. By using a lower temperature, the volatilisation of the potassium compound may be prevented.

Butyl Alcohol and Acetone. E. Ricard, Melle, Deux-Sèvres, France. British Patent, 130,666. Convention date, August 8, 1917.

Butyl alcohol and acetone are produced by fermentation of worts made from starchy materials by means of a special bacillus, named *bacillus butylicus* BF, found in animal refuse such as the liquid refuse of slaughter-houses. The bacillus, a description of which is given, is optionally anaerobic, and is cultivated and isolated by ordinary methods. It can be

used in worts which have been boiled with acid to aid liquefaction. The illustration shows a plant suitable for carrying out the process. The material is mashed in a mash-tun B, boiled in a boiler C, and mixed with water to the proper degree of dilution in a mixer D. The material thus treated is heated by steam to a temperature of about 120° C., and raised by steam-pressure to a reservoir E, whence it passes to the fermenting-vats G, G' through a heat-interchanger F, where it is cooled to 37° C. The hot water from the interchanger F is used in the mash-tun B and dilution vessel D. The fermenting-vats G, G' are provided with flexible connections 20, whereby fermented liquid can be passed from one vat into another to start fermentation. An appropriate quantity is about 5 per cent. of the contents of a vat. Pipe connections are provided whereby the apparatus can be sterilised by filling it with steam, which is afterwards replaced by sterilised air. The fermented liquid passes from the vats G, G' to storage chambers N, N', and thence to a still and rectification column O. The spent liquor from the still is used to heat the incoming liquor in a heat-interchanger P. The gases escaping from the condensers are freed from acetone in a washing-column Q.

Distilling Esters. U.S. Industrial Alcohol Company, New York, U.S.A. British Patent, 130,968. Convention date, August 7, 1918.

Esters are prepared in a continuous manner by feeding an alcohol, an organic acid, and a catalyst to a column still. The production of methyl acetate from methyl alcohol, dilute or

glacial acetic acid, and sulphuric acid is described. Using the apparatus shown in Fig. 1, sulphuric acid, dilute acetic acid, and methyl alcohol are fed continuously in regulated amounts from tanks 8, 12, 18 respectively by pipes 7, 11, 15

to a column still 1 of ordinary construction; at the commencement sufficient methyl alcohol is run in to seal all the plates in the still. Vapours of methyl acetate and alcohol pass off by pipe 22 to a dephlegmator 23; condensed alcohol runs back from the dephlegmator to the still by pipe 24, while methyl acetate vapours pass off by pipe 25 to a second column still 26. From this still the methyl acetate vapours pass by pipe 27¹ to a dephlegmator 28, condensed alcohol flows back by pipe 29 to the top of still 26, while the methyl acetate vapours pass on to a condenser 31. A pipe 27 leads methyl alcohol from the lower part of still 26 to the still 1. Water and sulphuric acid flow from the bottom of still 1 by a pipe 20. The apparatus shown in Fig. 2 is similar in all respects except the feed device. Sulphuric acid, acetic acid (in this case glacial), and methyl alcohol are fed from tanks 42, 46, 50 respectively to a mixing-tank 35 which contains a rotary stirrer 36, and after undergoing partial reaction in the mixing-tank, the mixture is fed to the still by pipe 34; an initial charge of methyl alcohol, as before, is fed to the still by pipe 50^a.

Calcium Nitrate. Nitrum Akt-Ges., Zurich, Switzerland. British Patent, 130,979. Convention date, August 6, 1918.

A concentrated solution of calcium nitrate is obtained from nitrous gases by neutralising with lime the acid solution obtained by dissolving the gases, and using the neutralised solution for further absorption. The neutralisation may be effected by passing the solution over limestone in the absorption-apparatus, or by adding lime or limestone to the solution outside the absorption-apparatus, the neutralised solution being returned thereto.

Treatment of Nitrosulphonic Acids. Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. British Patent, 130,966. Convention date, August 9, 1919.

A small quantity of nitric acid—for instance, less than 1 per cent.—is added to nitrosyl-sulphuric acid or to sulphuric acid which has been denitrated by boiling, and contains a small quantity of nitrogen oxide to render these acids incapable of attacking iron, so that they can be handled in iron apparatus or stored in receptacles.

Recovering Solvents. E. I. du Pont de Nemours and Co., Wilmington, Delaware, U.S.A. British Patent, 130,962. Convention date, August 8, 1918.

Volatile solvents are recovered from coated surfaces such as split hides and aeroplane wings by passing a current of air over the surface and passing the vapour-laden air through an absorbent consisting of a distillate boiling at 205-245° C. obtained from wood tar after it has been freed from its alcoholic and acid constituents. This absorbent is particularly applicable for recovering vapours of methyl, ethyl, and butyl alcohol, methyl and ethyl acetate, benzole, acetone, ethyl methyl ketone and ether.

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Fersan Islands Oil Company, Ltd.—Resolved September 11, confirmed September 29: That the company be wound up. J. Barber, 19, Basinghall Street, E.C., liquidator.

Scientific Manufactures, Ltd., London, W.C.—W. H. King ceased to act as receiver September 22.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W.1, whence further information may be obtained:—

British West Indies.

A firm of importers in Trinidad desire to represent United Kingdom manufacturers of Portland cement on a commission basis. (Reference No. 802.)

Belgium.

A business man, established for 30 years at Verviers, desires to obtain an agency for aniline dyes. (Reference No. 808.)

France.

An agent in Montauban (Tarn-et-Garonne) desires to obtain agencies for United Kingdom manufacturers and exporters of chemical manures, sulphate of copper, superphosphates, etc. (Reference No. 813.)

A firm of manufacturers' agents in Paris, with branches in Australia, Sweden, Poland, Finland, and Russia, desire to obtain agencies, on a commission basis, for United Kingdom manufacturers of heavy chemicals, nitrates, phosphates, and sulphates. (Reference No. 814.)

Germany.

A German inquirer desires an agency, on commission, for the sale of edible and technical oils. (Reference No. 821.)

A German inquirer desires an agency, on commission, or on his own account, for the sale of soap and oils. (Reference No. 824.)

Italy.

A firm of export agents in Genoa desire to obtain agencies for United Kingdom exporters of fish-oil, sesame and cotton-seed oil, pistachio-oil, hogs' grease, and vegetable and animal oils and fats. (Reference No. 828.)

A firm of insurance, forwarding, and shipping agents in Naples desire to obtain agencies for United Kingdom manufacturers of chemicals and dyes. (Reference No. 829.)

Spain.

A Spanish commission agent at Madrid desires to get into touch with United Kingdom firms dealing in chemical products. (Reference No. 838.)

Canada.

A firm of manufacturers' agents at Winnipeg desire to represent United Kingdom manufacturers of soap, from Port Arthur to British Columbia, on a commission basis. (Reference No. 791.)

BOOKS RECEIVED.

"Reminders for Company Secretaries," 4th edition; 11d., post free. "Private Companies," 9th edition; 1s. 4d., post free. London: Jordan and Sons, Ltd.

"Cardiff."—An illustrated handbook descriptive of the commercial and industrial advantages of the Welsh metropolis, and covering also its institutions, attractions, and general development. Publishers: The Business Statistics Company, Ltd.; 5s.

BRYANT AND MAY, LTD.—Dividend at the rate of 7 per cent. for the half-year on the preference shares, and an interim dividend of 4 per cent., free of income tax, on the ordinary shares for the half-year.

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London, 90%, 2s. to 2s. 1d.; North, 1s. 11d. to 2s.; 50%, 1s. 10d. to 1s. 11d.; North, 1s. 9d. to 1s. 10d. naked. Carbohc acid, crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 8½d. to 9d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch, 77s. 6d. to 80s.;

East Coast, 70s. to 75s., f.o.b.; West Coast, 62s. 6d. to 65s., f.a.s. Solvent naphtha, naked, London, 90-100%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-100%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha, naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthalene, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 5½d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid,

95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b. other ports. Sulphate of ammonia: home trade, October £20. 10s., November £20. 15s., basis 24½%. Nitrate of soda, £22. to £22. 10s.

FERTILISER MATERIALS. LIVERPOOL, THURSDAY.

Nitrate of soda continues firm, the quotation on spot for 95/96% quality remaining at £20. per ton, net cash, f.o.r. Liverpool, prompt delivery. East Indian bone meal: Shippers still maintain a firm attitude, the quotation for October-December shipment, being £17. 10s. per ton, net cash, ex ship Liverpool, for 4½% ammonia and 52% phosphates quality. On spot Liverpool, holders ask £16. per ton, net cash, for 4½% and 45% quality. Mineral phosphates are without alteration, and values at present are only nominal. Dried blood continues scarce, the nearest value being about 30s. per unit of ammonia per ton, net cash.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £105. 15s. to £106. cash; £106. 5s. to £106. 10s. three months; electrolytic, £115. to £122. Tin: Standard, £278. 15s. to £279. cash; £280. to £280. 5s. three months; Straits, £279.; English, £277. to £278. Lead: Soft foreign, £28. 10s.; English, £29. 10s. Spelter, £44.; hard, £31. to £32. Antimony, English regulus, 90%, £45. Aluminium £150. Nickel £205. delivered, packages extra. Quicksilver, £16. 10s. Bismuth, 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

TURPENTINE MARKET REPORT.

Messrs. James Watt and Son, Ltd., of 101, Leadenhall Street, London, E.C.3., report that the stocks of turpentine on October 11 were: American, 37,729 barrels, compared with 4,828 barrels at the corresponding date of 1918; French 506 barrels (63 barrels); and Spanish, 446 barrels (1,387 barrels). Deliveries during the week ended October 11 were 1,435 barrels against 579 barrels last year, and since January 1, 56,996 barrels, compared with 19,769 barrels in 1918. The price on Saturday last was 125s. per cwt., compared with 105s. at the corresponding date of last year. October-December delivery was quoted at 125s., and January-April (1920) 127s.

SWANSEA MARKET REPORT.

THURSDAY.

Tinplate prices are very strong on the basis of 38s. 6d. to 39s. per standard box. Copper active at £106. 10s. per ton prompt and three months. Tin firm at £283. 10s. cash and £284. 10s. three months. Lead: Spanish, £27. 15s. English, £29. per ton. Spelter, £43. 10s. per ton. Silver, 62½d. per ounce. Antimony nominal, with English regulus, 90%, £45. Nickel in strong movement at £205., including delivery London or equal. Aluminium, £150. Quicksilver, £19. 10s. per bottle. Palm oil on small offer: Lagos and Benin, £82.; hard, £80. Petroleum steady, and in fair demand: refined, 1s. 6½d. to 1s. 7½d. per gallon, in casks. Turpentine, quiet and easier at 126s. per cwt. Sulphate of copper remains dull at £40. per ton, f.o.b. Sulphate of ammonia is very steady at £20. 10s. per ton. Nitrate of soda, 21s. 9d. per cwt. in bags. Arsenic in better call at £60. per ton. Oxalic acid, 1s. 2½d. per lb. Pitch still remains scarce and dear at 62s. 6d. per ton ex ship. Copperas selling more freely round £3. 10s. per ton at maker's works. All seed oils are steady and sparingly offered.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

There is an active demand for all heavy chemicals both on home and export account, and prices as a whole are well maintained. Caustic soda and 58% alkali are steady at recent advance. Bicarbonate of soda, bags, £8. 5s. to £8. 10s. per ton. Chlorate of soda easy at 6d. per lb. Potash 1s. per lb. Bleaching powder dull at £17. per ton on rails. Roasted saltcake quiet at 70s. per ton in bulk carriage paid. Recovered rock sulphur £17. per ton in bulk on rails. Sulphate of copper is unchanged in position, and price nominal at £40. per ton f.o.b. Commercial hypo. soda steady at £16. 10s. rails. Phosphate of soda £27. per ton. Concentrated sodium sulphide, 60/65%, easier at £21. 10s. casks. Nitrate of soda scarce and firm at £60. per ton. Bichromate of soda is short on the spot, and resale lots higher at 9½d. per lb. White powdered arsenic is more freely offered, but price unchanged at £60. per ton. Yellow prussiate of potash dull at 1s. 9d. per lb. Soda dearer at 11d. per lb. Carbonate of potash 85% £103. per ton. Lead salts are in steady

request. White acetate at £83. and brown £68. per ton. Nitrate £56. Business is quiet in acetate of soda, and price easy at £50. per ton. Acetic acid is offering at lower prices. English brown acetate of lime is short on the spot, and price dearer at £12. per ton. Grey unchanged at £17. per ton. Miscible wood naphtha firm at 10s. 6d. per gallon. Oxalic acid is lower at 1s. 1d. owing to arrival of Continental supplies.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

An active inquiry for chemicals has been experienced since the resumption of railway transport business. The demand from the home trade has been more brisk, and that from the export trade has agreeably increased. The general situation has much improved since the termination of the railway strike. Bleaching powder has been more in request. For the home trade, £17. per ton is quoted, and for export, £15. to £18. per ton. Chloride of calcium has been in somewhat freer inquiry, and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has been much in demand for export and for home trade purposes. Prices are, £24. per ton for 76%; £22. per ton for 70 to 72%, and £19. per ton for 60 to 62%. Nitrate of soda has met with a steady inquiry, and is £21. to £22. per ton. Saltcake has been more in request, and is £6. 10s. per ton, in casks f.o.b. Soda crystals have been well inquired for, and are £5. 10s. per ton in 2cwt. bags f.o.r. at works. Bicarbonate of soda has again sold with some freedom, and is £8. 5s. to £10. per ton, according to terms of delivery. Borax has been in good request, and is scarce for prompt or early delivery. Makers are reported to be well sold for weeks ahead and prices have been advanced. Ordinary, is quoted at £50. per ton, and powdered at £51. to £52. per ton, in bags. Ammonia alkali has been freely inquired for, and is £6. 10s. to £6. 15. per ton, f.o.r. at works. Hyposulphite has been rather more in request, and is £16. per ton for ordinary, and £21. per ton for pea crystals, in 1cwt. kegs. Sulphite of sodium has been in moderate demand, and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals, in 1cwt. kegs. Bichromate of soda has been in fair request, and is 9d. per lb. Phosphate of soda has been but little called for, and is £25. per ton. Sulphide of sodium has been rather more in request, and is £20. per ton in casks, and £22. per ton in drums. Chlorate of potash has been in quietly steady demand, and is 1s. to 1s. 2d. per lb. Permanganate of potash has been in fair request, and is 3s. 3d. per lb. Sulphate of potash has been but little called for, and is £30. per ton. Carbonate of potash has sold rather freely, and is £100. per ton for 80 to 85%. Caustic potash has met with a fairly active inquiry, and has been in limited demand. It is £120. per ton. Nitrate of potash has been in very fair request, and is £55. to £60. per ton for refined, and £40. per ton for ordinary. Canadian potashes have again been quiet. First quality Montreal are £200. to £220. per ton, and second quality £190. to £210. per ton. Bichromate of potash has been in moderate request, and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been quiet, and is 1s. 9d. to 1s. 10d. per lb. Salammuniac has been in quietly steady demand, and is scarce. Prices have advanced, and are £95. per ton for first quality lump, and £85. per ton for second quality. Crushed is £5. per ton extra. Sulphate of ammonia has been in quietly steady demand, and is £20. 10s. per ton for October; £20. 15s. for November; £21. for December; £21. 7s. 6d. for January, 1920; £21. 15s. for February, and £22. per ton for March to May, 1920. Carbonate of ammonia has met with a fair inquiry, and is 6½d. per lb. Muriate has been but little in demand, and is £50. to £55. per ton, according to quality. Magnesia has sold more freely. Carbonate is £2. 5s. per cwt., and sulphate, £10. to £16. per ton, according to grade. Alum has been in good request, and is still in very limited supply. For home trade uses, £18. 10s. per ton is being quoted, and for export, £18. 10s. to £19. 10s. per ton. Aluminoferric has been very quiet, and is £8. 10s. to £12. per ton, according to quality. Sulphate of alumina has been but little called for, and is £12. to £17. per ton, according to grade. Sulphur has been in rather active demand. English flowers are £32. per ton; roll is £28. per ton, and rock, £22. per ton, in bags, f.o.r. Sicilian grades are: flowers, £28. per ton; roll, £22. 10s. per ton, and rock, £17. 15s. per ton. Cream of tartar has been in very fair request, and is £11. 15s. to £12. per cwt. Tartaric acid has been called for more freely, and is 3s. 1d. to 3s. 2d. per lb. Boracic acid has been more in demand, and prices are higher. Crystals are £80. per ton, and powdered, £82. per ton, in bags. In casks, from £2. to £3. per ton, more, is charged. Oxalic acid has had a quietly steady sale, and is 1s. 2d. to 1s. 3d. per lb. Citric acid has

again been in very fair request, and is 4s. 4d. per lb. White acetate of lead has had a limited sale, and is £85. per ton. Arsenic has been more inquired for, and is £60. per ton for white powdered. Sulphate of copper has been neglected. Business in this article has been affected by reports of large offerings of sulphate from Government stocks in France at low prices. Quotations at Liverpool are, £41. to £42. per ton for home trade uses, and £42. to £43. per ton for export, less 5%; in casks, f.o.b.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Wednesday.

During the past week matters have moved fairly steadily in the local chemical trade, and the demand for the heavy chemicals has shown an improved tone in certain directions. Most chemicals have been in good demand, and prices remain firm and without appreciable alteration; with, if anything, a lowering tendency with regard to saltpetre, which is now selling at £3. 2s. against £3. 4s. previously. Current quotations are:—Arsenic, £62. per ton, net, Glasgow; bicarbonate of soda, £9. 15s. and £10. 10s. per ton for 6-8 casks and 1cwt. kegs, net, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags; and borax crystals, £39. for 2cwt. bags, carriage paid; caustic soda, white, 70-72%, £24. per ton, net, Glasgow; chlorate of potash, 1s 1d. per lb., net, Glasgow; chlorate of soda, 8d. per lb., net, Glasgow; citric acid, 4s. 4d. per lb., 5%, Glasgow; cream of tartar 98%, £11. 10s. per cwt., net, Glasgow; paraffin wax, U.K. deliveries, 125° 6½d. to 6¼d.; 121-30, 5½d. to 5¾d.; 118-200, 5d.; 110-120, 4d. to 4½d.; and 98-102°, 4d. to 4½d.; salammuniac, £80. and £75. per ton, net, any port, for first and second lump respectively; salammuniac crystals, £85. per ton, net, Glasgow; saltpetre, £3. 2s., net, Glasgow; tartaric acid, 3s. 3d. per lb., 5% Glasgow.

Among the sea oils demand is good and the general feeling of the market regarding prices is still firm and steady. Indeed, as far as quotations are concerned there are no changes, and

among the whale oils pale is still selling at 95s., brown at 76s., and black at 74s., with the yellow variety still being conspicuous by its absence. Newfoundland cod is changing hands at the old rate of 80s.; pale seal is quotable at 96s. as previously; while likewise there is no change on Menhaden at 82s.

In the West of Scotland coal trade there is little change to be recorded. With the colder weather there has been a bigger demand for fuel for household and other purposes, and with industrial matters moving more steadily the output is being cleared from the pitheads much quicker than during the past two weeks.

TYNE CHEMICAL REPORT.

TUESDAY.

Trade continues very brisk, and there is an improvement in the demand both for home and export market, caustic soda and bleaching powder in particular being in good request. Soda crystals locally are firm at £5. 10s. per ton, 2cwt. bags. Sulphur is still very scarce at £22. to £23. per ton, in bags.

The following prices are per ton, net: Bleaching powder, softs, £17.; caustic soda, 76-77%, £23. 5s.; do., 70%, £22.; do., 60%, £20.; recovered sulphur, 2cwt. bags, £22.; hypo-sulphite of soda, 5-7cwt. casks, £19.; do., 1cwt. kegs, £25.; sulphite of soda, 5-7cwt. casks, £12.; do., 1cwt. kegs, £20.; silicate of soda, 75° Tw., £9. 12s. 6d.; do., 100° Tw., £10.; do., 140° Tw., £10. 10s.; soda crystals, 2cwt. bags, £5. 10s.; sulphate of soda (saltcake), £4.; pure white sulphate of alumina, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18.; do., refined concentrated solid, 60-62%, £25.; hydrate of barium, crystals, £56.

COALS.—Market is firm, and for the moment there is a rather larger supply of coal, owing to general shortage of tonnage and licence regulations. Prices are nominally: Best Northumbrian steam, 95s. to 100s. per ton; seconds, 85s. to 90s.; Northumberland small coals, 75s. to 80s.; seconds, 70s. to 72s. 6d.; best Durham gas coals, 80s. to 85s.; seconds, 65s. to 75s.; Durham bunkers, 70s. to 80s.; seconds, 65s. to 67s. 6d.; foundry coke, 100s.; gas coke, 95s. to 100s.

Swettenham, 1 t. 8 c., £62.; Puerto Barrios, 2 t. 6 c., £75.; St. Lucia, 7 c., £26.; Sandakan, 1 t. 17 c., £95.; Suez, 4 c., £11.; St. John's, N.F., 1 t. 13 c., £60.; Wellington, 7 c., £21.

ETHER—
Beyrou, 6 cs. (pt.), £7.; Calcutta, 27 pkgs. (pt.), 1 cs., £14.

ETHER (ACETIC)—
Bombay, 1 cs., £9.

ETHER (OZONIC)—
Bombay, 1 cs., £8.

ETHER (SULPHURIC)—
Alexandria, 2 cs., £50.; Bombay, 1 cs., £6.

ETHYL CHLORIDE—
Durban, 1 cs., £7.

FATTY ACIDS—
Nantes, 38 t. 10 c.

FERRO TUNGSTEN—
Rotterdam, £4,080.

FORMALDEHYDE—
Alexandria (F.), 3 cs., £42.; Antwerp, 5 cks., £134.

GLUE, SIZE, AND GELATINE—
Antwerp, 2 c.; Bombay, 1 t. 8 c.; Brisbane, 1 t. 7 c.; Calcutta, 1 c.; Cape Town, 1 c.; Dunedin, 1 c.; Durban, 8 c.; East London, 1 t.; Hong Kong, 1 t.; Karachi, 14 c.; Kobe, 4 t.; Madras, 1 t. 7 c.; Melbourne, 2 c.; Rotterdam, 57 t. 5 c.; Shanghai, 1 c.; Stockholm, 2 c.; Sydney, 1 t. 15 c.; Trinidad, 1 c.

GLYCERINE—
Alexandria, 5 c., £35.; Amoy, 1 c., £8.; Bangkok, 1 c., £8.; Bombay, 1 c., £7.; Calcutta, 2 c., £25.; Cape Town, £6.; Danzig, 5 t., £630.; Durban, 10 c., £59.; Galatz, 3 c., £22.; Peking, 1 c., £7.; Piraeus, 6 c., £45.; Pt. Elizabeth, 1 t. 13 c., £195.; Shanghai, 1 c., £14.

HYDROCHLORIC ACID—
Bombay, 1 c., £6.; Durban, 8 c., £44.

HYDROFLUORIC ACID—
Bombay, 1 cs., £17.; Durban, 1 cs., £6.

HYDROGEN PEROXIDE—
Alexandria, 2 cs., £12.; Beira, 1 cs., £5.; Durban, 2 cs., £13.; Paris, 5 cks., £40.

HYDROXIDE—
Karachi, 1 cs. (pt.), £15.

IODINE—
Boulogne, (F.), 9 cks., £4,775.

IRON & AMMONIUM CITRATE—
Buenos Ayres, 1 cs. (pt.), £6.; Calais, 3 cs. (pt.), £68.; Durban, 1 cs., £6.; Sydney, 1 cs. (pt.), £11.

IRON AND POTASSIUM TARTRATE—
Calais, 3 cs. (pt.), £25.

LACTIC ACID—
Genoa (F.), 1 ck., £70.; Sydney, 26 cks., £156.

LEAD SULPHATE—
Bombay, 8 cks., £160.

LITHIUM CARBONATE—
Bombay, 1 cs. (pt.), £6.; Boulogne (F.), 1 cs., £43.

MAGNESIA—
Alexandria, 3 cs., £22.; Brussels, 1 cs., £17.; Lisbon, 50 bgs., £70.

MAGNESIUM CHLORIDE—
Montreal, 4 drms., £29.

MAGNESIUM CITRATE—
Beyrou, 5 cs. (pt.), £7.

MAGNESIUM OXIDE—
Boulogne, 1 cs., £11.

MAGNESIUM SILICATE AND FLUORIDE—
Copenhagen, 1 brl., £19.

MAGNESIUM SULPHATE—
Bombay, 1 t. 4 c., £56.; Calcutta, 8 c., £28.; Cartagena, 10 c., £24.; Durban, 10 c., £10.; Karachi, 4 c., £11.; Newcastle, N.S.W., 1 t. 3 c., £46.; Panama, 6 c., £16.; Paris, 1 t., £29.; Peking, 5 c., £8.; Sydney, 10 c., £10.

MAGNESIUM SULPHATE (GLAUBER SALTS)—
Cartagena, 11 c., £5.

MANGANESE BORATE—
Amsterdam, 3 c., £29.

MANGANESE SULPHATE—
Stockholm, 1 ck., £76.

MERCURIALS—
Sydney, 1 cs. (pt.), £15.

MERCURY BICHLORIDE—
Beyrou, 11 cs. (pt.), £12.

MERCURY PERCHLORIDE—
Colombo, 1 cs. (pt.), £5.

MERCURY SUBCHLORIDE—
Calcutta, 1 cs., £42.

METHYL SALICYLATE—
Beyrouth (F.), 5 cs. (pt.), £6.;
Constantinople (F.), 1 cs., £22.

METHYLENE BLUE—
Calcutta, 1 cs., £8.

MINERAL WAX—
Galatz, 4 t.

NICKEL CHLORIDE—
Italy, 1 ck., £16.

NITRIC ACID—
Bombay, 1 c., £7.; Durban, 6 c.,
£36.

PARAFFIN WAX—
Antwerp, 1 t. 4 c.; Genoa, 20 t.

PARALDEHYDE—
Calcutta, 1 cs. (pt.), £7.

PHOSPHORIC ACID—
Bombay, 2 cs., £18.; Calcutta,
1 cs., £7.; Melbourne, 4 cs., £39.;
New York, 38 pkgs., £170.;
Paris, 8 cs., £36.; Sydney,
89 cs., £374.

PLUMBAGO—
Constantinople, 2 c.; Marseilles,
1 t.

POTASSIUM ACETATE—
Sydney, 1 cs (pt.), £5.

POTASSIUM BICARBONATE—
Brussels, 10 cks., £61.

POTASSIUM BICHROMATE—
Danzig, 5 t., £790.

POTASSIUM BROMIDE—
Calcutta, 2 cs. (pt.), £19.;
Colombo, 1 cs. (pt.), £9.

POTASSIUM CARBONATE—
Alexandria, 3 cs., £32.; Brussels,
1 kg., £15.; Bombay, 1 kg. (pt.),
£7.

POTASSIUM CITRATE—
Bombay, 4 cs., £67.; Calcutta,
1 cs. (pt.), £7.; Singapore, 3 cs.
(pt.), £7.; Sydney, 1 cs. (pt.), 3
cs., £101.

POTASSIUM CYANIDE—
Buenos Ayres, 1 cs., £10.;
Constantinople, 2 cs., £66.

POTASSIUM HYDROXIDE—
Calcutta, 27 pkgs. (pt.), £10.

POTASSIUM IODIDE—
Beyrouth, 6 cs. (pt.), £11.;
Calcutta, 1 cs. (pt.), £20.;
Danzig, 5 cs., £336.; Naples,
3 cs. (pt.), £85.

POTASSIUM METABISULPHITE
Bombay, 10 cks., £145.; Paris,
8 cks., £422.

**POTASSIUM OXIDE, AND
HYDRATE**—
Rangoon, 1 cs. (pt.), £19.

POTASSIUM PERMANGANATE—
Alexandria, 1 cs., £24.; Con-
stantinople (F.), 2 cs., £42.;
Constantinople, 2 cs. (pt.), £19.;
Danzig, 36 cs. (pt.), £96.;
Perth, 1 c., £18.; Rangoon, 1 cs.
(pt.), £5.

POTASSIUM PHOSPHATE—
Demerara, 25 t., £625.

POTASSIUM PRUSSATE—
Colombo, 1 cs., £12.

POTASSIUM SULPHIDE—
Melbourne, 2 cs., £14.

SALAMMONIAC—
Alexandria, 2 c., £9.; Constanti-
nople, 2 t. 11 c., £254.; Durban,
5 c., £18.; Salonika, 2 t. 2 c.,
£168.

SALICYLIC ACID—
Bombay, 1 cs., £5.; Sydney,
1 cs., £7.; Switzerland, 20 cks.,
£112.

SALPETRE—
Barcelona, 3 t., £165.; Bilbao,
26 t., £1,248.; Buenos Ayres,
6 t. 9 c., £368.; Durban, 10 c.,
£29.; Gijon, 1 t., £55.; Lisbon,
12 t. 2 c. (F.), £428.; Lisbon,
5 t. 17 c., £315.; New York, 50 t.
(F.), £1,929.; Panama, 2 c., £7.;
Salonika, 2 c., £11.; Toronto,
5 t., £300.

SHEEP DIP—

Beira, 4 c., £29.; Buenos Ayres,
2 c., £6.; Durban, 4 t. 9 c., £396.

SILVER NITRATE—

Constantinople, 1 cs. (pt.), £30.;
Rangoon, 1 cs. (pt.), £5.

SILVER PROTEINATE—
Buenos Ayres, 1 cs. (pt.), £5.

SIZE—

Montreal, 4 c.

SOAP—

Aden, 1 c.; Alexandria, 1 t. 2 c.;
Amsterdam, 3 t.; Antwerp,
138 t. 10 c.; Auckland, 2 c.;
Bangkok, 4 t. 6 c.; Bordeaux,

SODIUM BISULPHITE—
Antwerp, 2 t., £59.

SODIUM BROMIDE—
Danzig, 36 cs. (pt.), £125.

SODIUM CITRATE—
Calcutta, 1 cs. (pt.), £11.;
Sydney, 1 cs., £22.

SODIUM CYANIDE—
Bilbao, 4 cs., £32.

SODIUM FORMATE—
Barcelona, 1 cs., £21.

SODIUM GLYCEROPHOSPHATE—
Gothenburg, 2 cs., £26.

SODIUM IODIDE—
Constantinople, 1 cs. (pt.), £11.;
Danzig, 1 cs., £93.; Naples,
3 cs. (pt.), £60.

SODIUM PHOSPHATE—
Calcutta, 3 c., £6.

SODIUM PRUSSATE—
Kobe, 14 t. 19 c., £1,138.

SODIUM SALICYLATE—
Bombay, 1 cs., £5.; Calcutta,
1 cs., £10.; Rotterdam, 2 cks.,
£70.; Sydney, 4 cks., £42.

SODIUM SILICATE—
Durban, 1 t. 9 c., £71.; Gothen-
burg, 8 t. 1 c., £128.

SODIUM SULPHIDE—
Boulogne, 22 t. 13 c., £383.

SODIUM SULPHITE—
Antwerp, 2 t., £72.; Sydney,
2 t., £70.

SODIUM TARTRATE—
Melbourne, 1 t., £114.

SPERMACEITI WAX—
Genoa, 14 c.

SULPHUR—

Amsterdam, 1 c., £5.; Dantzig,
2 t., £160.; Hankow, 6 c., £13.

SULPHUR CHLORIDE—

Barcelona, 2 drms., £54.

SULPHURIC ACID—

Bombay, 1 c., £6.; Calcutta,
27 pkgs. (pt.), £16.; Durban,
6 c., £30.

SUPERPHOSPHATES—

Colombo, 50 t.
Genoa, 31 t. 3 c.; Rotterdam,

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers) ..	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

EDITORIAL NOTICES.

Readers are invited to forward items of intelligence, company reports and balance-sheets, or cuttings from local newspapers of interest to the trades concerned.

CURRENT TOPICS.

STANDARD METHODS OF ANALYSIS.

NOT the least interesting portion of the paper by Mr. Arnold Philip, read at a meeting of the Institution of Petroleum Technologists this week, was his reference to the standardisation of methods of testing materials. In one or two branches of analytical work attempts to effect some standardisation of methods have been persistently made for some time, but the wider growth of the movement is a matter of comparatively recent development. So far as the testing of petroleum products in particular is concerned, the position has been very ably summed up by Mr. Alexander Duckham, who, a short time ago, stated that even in the simplest tests, carried out on well standardised apparatus, there will be found to be variations in results in the hands of different operators, this being due to small differences in manipulation. Apart from the standardisation of the actual methods of testing is the policy of issuing standard samples of materials, in this case the method of testing being left to the choice of the individual analyst. The recognised standards are then used as a check upon the various methods employed. This procedure, as our readers will be aware from recent articles published in these columns, has been adopted in the case of iron and steel analysis. As the result of a conference convened by the Institute of Chemistry a few months ago, and attended by representatives of other bodies, the matter was carried a good deal further by the decision that the preparation and issue of authoritative samples of chemical substances, metals, etc., of ascertained composition was desirable. Moreover, it was decided that as such standards could not be provided without reference to methods of analysis the scheme should not aim at restricting the choice of methods but always their revision and improvement. Because of the difficulties inherent to the storage and transmission of a sample of oil large enough to carry out a complete set of tests, Mr. Philip did not consider the policy of issuing standardised samples feasible in respect of the testing of mineral oils, although, at the same time, he recognised the necessity for effecting a standardisation of the methods of testing employed. This latter view received a great measure of

support, as will be seen from the report of the discussion on another page. "One objection to the standardisation of methods consists," said the author, "in the real difficulty which is experienced in describing any method of test in such a way that different operators having different experiences in testing will all apply it in the same manner. It is believed that most chemists who have had experience of the difficulties in testing on the large scale must have realised that although a method of test used in a given laboratory may as a general rule be carried out in the same manner, yet even under such conditions, with a large staff of analysts, the members of which change from time to time, a good deal of careful supervision is required in order to secure that the routine of testing is carried out in all its necessary detail, even although full written instructions for the methods are supplied for information. Usually, these must be supplemented by direct verbal instruction. If this is true of one large laboratory it must prove a still more difficult matter to secure uniformity of method of test by means of written instruction in all laboratories." That difficulty is certainly a real one, but it is also one that might very easily be exaggerated. At any rate, we do not think it formidable enough in itself to render a system of standardisation unworkable.

SITES FOR CHEMICAL WORKS.

MR. JOHN ALLAN, on Tuesday, delivered the first of two lectures on "Site, Lay-out, and Construction of Chemical Plant," at the College of Technology, Manchester. The lecturer confined his remarks to the consideration of the choice of a site for a works, with particular reference to finished products, raw material, fuel, water, and labour supply, and to the disposal of the trade effluents.

Closely involved in the selection of a suitable site, said Mr. Allan, was the question of transport facilities, and the more favourable these were, particularly with regard to the carriage of imported raw materials, the more suitable, as a general rule, the site. Rail or waterway connection with the port of entry of the imported material was a distinct advantage. A method of conducting raw material to the works which was often lost sight of was by means of pipe-lines, and reference was made to the establishment of works in the salt areas. Salt was a very essential material in the processes carried on at those works, but by the adoption of pipe-lines for the purpose of conducting the brine long distances, some of the factories could very well, having regard to the many other factors involved in the selection of a site, have been advantageously set up in districts more suitable in numerous ways. The supply of coal was a question which should be dealt with in conjunction with that of raw materials, and the site of a works for the manufacture of chemical products was in a large measure determined by the balance which could be struck between the cost of bringing raw materials into the works and the cost of bringing coal. It should not be forgotten also that fuel was to be used for various other purposes, and it might be necessary to decide which particular class of coal they were going to locate their works near. In certain cases where the consumption of coal was a large factor in the chemical processes which were being carried

out it might well be good practice to transfer the works bodily to where the coal was readily available, in spite of the frequent necessity for carrying other articles that were required at high, or even excessive, costs.

A cheap supply of electricity was very often an important consideration, and the nature of the operations carried out in the works would determine whether electricity at low rates would be a decisive factor in the location of a works. In this respect Mr. Allan instanced the case of a large factory making caustic potash on a big scale. The factory referred to was situated on the banks of a river right in the heart of an agricultural area, and it was there simply because electricity and labour were cheap. The works had easy connection by barges for their product, and the potassium chloride used in the process was supplied to them also in barges. Such a works, by virtue of the process, was, of course, peculiarly well situated for adopting a site of that type.

It was important that a suitable supply of water should be available, and it often happened that that which was quite satisfactory for purposes of steam-raising could not be used in the processes for the manufacture of chemicals. In that case, Mr. Allan suggested, river water could be used for the boiler plant, and the public supply, or, preferably, condensed water produced in the works, for manufacturing purposes. A very difficult and complex problem was presented in disposing of the effluents arising from chemical processes. As an example, it was stated that whilst an effluent from a chemical works might not in itself be harmful, yet if it were discharged indiscriminately into a stream without considering the effect of its admixture with discharges from other works serious consequences might result. Trouble might also follow if certain effluents were sent down the drains without care being exercised. There were other forms of effluents arising from the solid wastes. It sometimes happened that certain solid wastes which were discharged on to a tip produced effects which were detrimental. Moreover, the location of the tip should be taken into consideration. A certain works close to Manchester, concerned with the manufacture of caustic soda, was depositing waste containing small quantities of caustic soda which could not be profitably recovered. That waste was deposited in a heap in what seemed a desirable place for it. Some time after a peculiar disturbance was noticed in a stream a considerable distance away from the heap. Between the stream and the waste deposit ran a canal, and finally it was shown that the drainage from the heap was finding its way underneath the intervening canal and thus affecting the stream. So much was the right of the riparian owner concerned that it was necessary to take all possible precautions with regard to contamination.

In conclusion, Mr. Allan stated, with regard to the supply of labour, that it was of no use erecting a chemical works in a district where labour was practically unobtainable, unless the owners were in a position to house their workmen and thus attract labour from outside districts. Dealing with the actual erection of the works, first of all the constructional materials should be available cheaply, for the cost of plant and buildings was a capital charge on the process, although, at the same time, the buildings themselves should be of a substantial character. Careful investigation should also be made before heavy buildings or plant were erected, and drilling to determine the nature of the soil should not be scamped, as a weak foundation might be discovered which would be affected by heavy buildings or plant.

NEW LIGHT ON SULPHUR.

Some Microscopical Crystallisations.

By JAMES SCOTT.

THE allotropicism of sulphur has always afforded investigators plenty of scope for making fresh discoveries; and even now, although new facts have been learnt concerning the modifications of the element, it appears that finality in this respect has not been reached. The latest assumption, based on very careful observation, is that beside the better known, more conspicuous, rhombic, prismatic, octahedral, and plastic forms of sulphur, there are at least two, and probably three or four, others. For my own part, I think that the number could be easily added to by men who will make the requisite experiments.

A nacreous form of sulphur can be obtained by heating the element to 150°C ., then cooling it to 98°C ., and scratching the tube containing it with a glass rod. Lustrous needle crystallisation is then induced. A very peculiar colloidal form of sulphur is obtainable by adding a solution of sodium thiosulphate (hypo) to cold sulphuric acid. The liquid is then diluted, heated, and filtered through glass wool. The result is that a cloudy yellow

tions which are traceable in it. It has been reasonably concluded that there are at least two distinct modifications or dynamic isomerides, and these are now termed $\text{S } \lambda$ and $\text{S } \mu$. They appear to depend principally upon the influence of temperature. $\text{S } \lambda$ is comparatively mobile, and stable below a temperature of 160°C . $\text{S } \mu$ is viscous and dark. All liquid sulphur contains both of these phases up to a definite temperature, when changes begin to manifest themselves. $\text{S } \mu$ is completely dissolved in $\text{S } \lambda$, and equilibrium is maintained at temperatures below 160°C . The two kinds are, however, only partly miscible in each other under certain circumstances.

At a temperature of 160°C a saturated solution of $\text{S } \mu$ in $\text{S } \lambda$, and a saturated solution of $\text{S } \lambda$ in $\text{S } \mu$ are evident. Above 160°C only $\text{S } \mu$ is stable, and the percentage of $\text{S } \lambda$ decreases as the temperature rises. The changes can be retarded or accelerated by means of the action of various compounds, but a consideration of this side of the subject does not come within my present purview.

No. 1.—One twenty-fourth inch of a layer of sulphur slowly cooled from the molten state between two glass slides; magnified.

No. 2.—One twenty-fourth inch of a layer of sulphur rapidly cooled from the molten state between two glass slides; magnified.

No. 3.—One twenty-fourth inch of a layer of sulphur suddenly cooled from the molten state between two glass slides; magnified.

mass is left, which upon the application of warmth becomes quite clear and transparent. But as it cools it again becomes turbid. If the mass is separated by means of a centrifuge, some remarkable tests may be made upon it.

From direct observation of the precipitate of sulphur produced in this reaction—*viz.*, sodium thiosulphite and acid,—I find that the sulphur occurs in the shape of minute, glistening, translucent globules, without any obvious crystalline structure. It is no doubt due to some difference between the "skins" of these globules and their internal portions that alternate cloudiness and clearness follows, according to whether the fused mass is cold or hot, because the "skins" must be locked up in the enveloping remainder. Heat reduces them to the same composition as the remainder, but as the mass cools it tends to resolve itself into a cellular form, and the "skins" must then resemble "walls" of the united globules.

Everyone who has examined the subsequent conduct of molten sulphur must have been struck by the varia-

The solid form of $\text{S } \lambda$ is crystalline, and it is soluble in carbon disulphide. On the other hand $\text{S } \mu$ is amorphous, and insoluble in the solvent just named.

When common sulphur is heated the quantity of sulphur dioxide which has arisen, owing to the combination of oxygen with it, retards some of the alterations, and the result differs slightly from that obtained in the laboratory when pure sulphur is dealt with. When the pure element only is used no amorphous sulphur is detectable by rapidly cooling it from its boiling point.

It is only to be expected that disputes are still prevalent in connection with some of these matters; more especially over the melting and freezing points. The latter, for instance, are divided into the *natural* and *ideal freezing points* respectively. The *natural freezing point* of $\text{S } \lambda$ and $\text{S } \mu$ is 114.5°C ., and the mixture then contains 3.7 per cent. of $\text{S } \mu$. The freezing point varies, however, with the proportion of $\text{S } \mu$ sulphur present in the molten state, and the species of solid tested. The following are reliable figures bearing upon the *ideal freezing points* of sulphur wholly devoid of $\text{S } \mu$, and the

natural freezing points of sulphur when the usual equilibrium portion of S_{μ} is present—in other words, after common sulphur has been melted:—

Solid Sulphur.	Natural Freezing Point.	Ideal Freezing Point.
Rhombic S or alpha sulphur	114.5° C. (3.6% S_{μ})	119.3° C.
Prismatic S_2 or beta sulphur	110.2° C. (3.4% S_{μ})	112.8° C.
Nacreous S_8 or gamma sulphur	103.2° C. (3.1% S_{μ})	106.8° C.

A few years ago attempts were made to establish the identity of a form of sulphur called S_{π} , which is deep yellow. A saturated solution of sulphur in sulphur chloride at ordinary temperatures will, of course, take up no more sulphur, yet when the solution is heated to 150° C. and then cooled, quite a lot more of the element can be absorbed in the solution. Since this phenomenon is still in the controversial stage I will not further dwell upon it.

It is claimed that a fourth modification of sulphur is procurable—viz., S_{ϕ} . Add hydrochloric acid at zero to a cold solution of sodium thiosulphite, and then shake the solution with toluene. After a short time S_{ϕ} will separate from the toluene as orange-coloured crystals.

Judging from the preceding details, it would seem that as sulphur loses its yellowness and tends to become brown the original amount of S_{λ} is permanently converted into S_{μ} . But we cannot be sure on this speculative phase. When molten sulphur in its red-brown state is poured into cold water it becomes plastic and non-crystalline; but this form, if removed, dried, and kept awhile, gradually changes into the bright yellow, brittle, and crystalline form. Intricate problems are involved in the study of these alterations, and it would be necessary almost hourly to examine thin layers of this plastic sulphur for a long period—until it had changed into the crystalline stage—to be able to say what really happens in it.

Now, whatever may be one's opinions upon these things, the study of sulphur changes, from the molten to the solid condition, is very attractive if it is assisted by the microscope. I will recount my own experiences while adopting a plan which I believe originated with me—that is, to keep the sulphur between two glass slides. The pressure thus exerted may be compared to that which must occur in a mass of sulphur as it is solidifying from the molten state, yielding formations which cannot, of course, be observed meantime.

I began by heating some flowers of sulphur on ordinary micro-slides, and when this was molten I pressed another slide—a cold one—upon the fluid sulphur. Following this, some sulphur was melted between two glasses and allowed to cool without additional pressure. I made some dozens of tests, but will describe only the main results. Not only can the structural detail be varied according to rapidity of melting and length of the heating period, but a great deal depends on whether it is allowed to cool and solidify in warm or cold surroundings.

If the molten sulphur is cooled slowly between two glasses, both of which were at first hot, it crystallises by the development of the slenderest possible needle-groups. The figures flow, as it were, quickly across the transparent fluid, and turn it into an opaque solid. This result can be hastened by touching the molten sulphur—this time melted on one glass only—with a needle-point. Almost instantaneous solidification occurs. This result is shown in No. 1.

If the molten sulphur is pressed by a cold slide it quickly solidifies into one or another striking crystalline series of forms. In No. 2 is shown that which most usually arises, the crystals often being very symmetrically arranged. In many cases these results are exceptionally fine, and dendritic to the extreme. A variety of dimensions occurs in a small space.

Octahedral (with suppressed features) and kindred rhombic forms can also be obtained, but have to be carefully manipulated for. Some are shown in No. 3. The more sudden the change the more likely are they to appear. Either of these forms can soon be changed into the other, and may sometimes be found together in the space of a single inch. Smaller quantities of sulphur yield different results from larger ones. Sometimes needles and prisms cross one another in an entangled manner.

I noticed that even when the molten sulphur was brown it became yellow after pressure.

I melted some sulphur on glass and tilted and moved the hot slide to and fro for some time. Some of it, as globules, could be made to travel in and out among others which had hardened and become stationary. This aspect is worth following up.

Some of the cooled sulphur, even when pressed, consists solely of clusters of minute globules. Other portions are so finely crystalline as to be practically amorphous. The films of sulphur will often be surrounded by distinct white margins, very wide, due, no doubt, to partial oxidation.

Quite an interesting set of crystal formations can be obtained in the manner suggested.

LOW-TEMPERATURE DISTILLATION.

A PROCESS for low-temperature carbonisation which has attracted more or less notice in British Columbia has been experimented with at Nanaimo under the auspices of the inventor, Walter Thomas, and a Vancouver firm, McPherson and Fullerton Brothers. Originally it was tried on Nicola Valley coal; the products were a semi-coked smokeless fuel, and about 7 gallons of oil per ton of fuel, with little permanent gas. Later work, according to *Chem. and Met. Eng.* (New York), has produced a good dense charcoal from mill waste obtainable for a few cents per cord. In operation, a vertical brick-lined retort some 14ft. high and 3½ft. in diameter is filled with coarse material to be carbonised, then closed, and the air contained in the system forced by a fan through a pipe stove and into the top of the retort. This passes down through the mass to be carbonised, thence through a pipe condenser and an electrical precipitator to remove liquid hydrocarbons, and back to the fan for recirculation. As the carbonised fuel becomes hotter, gases will be given off so that after a time rich distillation gas should constitute the circulating medium.

Dr. Stansfield in his recent report on "Electric Smelting of Iron Ore in British Columbia" presents a short note on this process. He sees many drawbacks to the scheme as it was illustrated to him, such as the difficulty of forcing gas through the field retort, the slow heating of the carbonising mass by the circulating gases, which are of low temperature and low heat capacity, the inefficiency and expense of the ordinary pipe stove, and the decomposition of hydrocarbon which will take place at this point.

LABORATORY TESTS ON MINERAL OILS.*

By ARNOLD PHILIP, B.Sc., F.I.C.

AS a preliminary to the discussion of methods for the chemical testing of oils, it is necessary to make some remarks upon the method of preparing samples for laboratory tests. It must be assumed in the first place that the bulk-sample of oil, as received in the laboratory, really represents correctly the contents of the land storage or steamer-tank from which it has been drawn. The author is accustomed to adopt a routine procedure for preparing representative samples for test for all opaque or dark-coloured oils, creosotes and tars, and it cannot be insisted upon too strongly that, unless satisfactory precautions of this character are taken, all tests made on such oils may be to a large extent illusory. The procedure of preparing representative samples need not generally be rigidly followed in the case of transparent oils, whether these are motor spirits, kerosenes, creosotes, or crude oils, for when an oil is transparent the amount and distribution of any separated water or emulsion can be observed by inspection, and a more convenient and shorter method of measuring the separated water and preparing the representative sample is evidently usable. In all cases, however, it is necessary to prepare representative samples by some suitable procedure.

PREPARATION OF REPRESENTATIVE SAMPLES.

I. *Liquids possessing a density less than that of water.*—The bulk-sample on receipt is allowed to stand in the laboratory in its containing vessel at the room temperature without shaking for at least 17 hours—i.e., overnight. The vessel is then tilted, so that any separated water may collect together in an increased depth at one side at the bottom. The end of a long-stemmed 100 cc. pipette is next inserted, so as to reach to the bottom of the vessel at the side where the water has been caused to collect, and a quantity of the sample, measuring about 100 cc., is withdrawn for inspection. If no water is observed in this sample it is returned to the vessel. The whole sample is then thoroughly mixed by shaking, and the amount necessary for carrying out the requisite tests, designated *Sample A* in the following paragraphs, is withdrawn and tested as desired.

If, however, visible water, other than small drops adhering to the pipette, is observed, the 100 c.c. is returned to the containing vessel, and the whole of the bulk-sample is again allowed to stand and settle for a further period of about 17 hours. At the end of this second period three-quarters of the settled bulk-sample is cautiously decanted off, all shaking being as far as possible avoided. This decanted three-quarters of the original bulk-sample is designated *Sample B*. The remaining one-quarter of the bulk-sample left in the containing vessel, designated *Sample C*, is then poured into a large separating funnel, and the *Sample B*, which was first decanted off, and which has thus been freed from the greater portion of the larger bubbles of water, is returned to the original vessel and well shaken up, and then, like *Sample A*, used for the necessary tests.

The *Sample C* containing most of the separated water and emulsion is allowed to stand in the separating funnel for 17 hours, when all the visible emulsion and water and about one-quarter of the remaining oil is run off from the funnel and mixed with an equal volume of wet kerosene, in order to cause a more complete separation

of the water. After this kerosene mixture has been allowed to stand overnight the volume of the separated water is measured, and this, together with the mixture of oil and kerosene, is transferred to a properly labelled bottle and retained for future reference if necessary. The amount of water found in *Sample C* as described above is calculated as a percentage on the whole of the original bulk-sample, and reported as *Visible Separated Water*.

II. *Liquids possessing a density equal to or above that of water.*—Creosotes and tars usually possess a density greater than unity, and the separation of water by gravity from such liquids either does not take place at all or is extremely slow. This is particularly observable with coal-tar creosotes and low-temperature coal-tars, whose density is only slightly greater than that of water. In transparent creosotes large globules of water may sometimes be observed immersed in the creosote, and neither rising nor falling. In tars which have been obtained by high-temperature distillation, and which have higher gravities, the separation of the water on standing usually takes place at the top of the sample.

For creosotes and low-temperature tar the best method of preparing a representative sample is to proceed as for *Sample A* in Section I. For dense tars a suitable modification of the procedure described in Section I. may be employed, making the necessary alterations indicated by the water being separated on standing at the top instead of at the bottom of the sample.

DISTILLATION TESTS ON CRUDE OILS.

Mineral oils may be divided roughly into the three following groups:—

I. *Petroleum Oil Group*, including: (a) crude petroleum; (b) petrol spirit; (c) turpentine spirit; (d) kerosene; (e) solar oil, gas oil, spindle oil; (f) mineral lubricating oil; (g) petroleum residuum oil.

II. *Shale Oil Group*, including: (a) crude shale oil; (b) shale spirit; (c) shale burning oil; (d) shale gas oil; (e) shale lubricating oil.

III. *Tar Oil Group*, including: (a) tar; (b) benzole; (c) middle oil; (d) creosote oil; (e) anthracene oil.

It is important to notice that the problem of testing the crude oils of each of these three groups is radically different in its nature from that involved in the testing of the other members of the groups. That this is so, may be readily recognised when it is considered that the partially or completely refined members of these groups marked (b) to (g) are supplied to some more or less definite specification, and they are therefore tested to ascertain whether they conform to this specification or not. But crude petroleum is a natural product, the composition of which is in no way controlled by human agency.

For technical testing purposes it is of the greatest importance that a method of fractionation shall be selected which will give the most uniformly concordant results when the same sample of mixed liquids is submitted to it by repeat tests either by the same or by different operators. It is also clearly most desirable that standard methods of fractional distillation tests shall occupy as short a time to carry them out as is possible, consistently with the condition that satisfactorily accurate and uniform results are obtained. Given a sufficient degree of accuracy, it is also desirable that such tests shall be capable of being carried out on small volumes of liquid. A further fact which must be taken into consideration when dealing with the fractionation of

* Abstract of paper read at a meeting of the Institution of Petroleum Technologists in London on Tuesday.

liquids which are liable to be partially decomposed or cracked at or near their temperature of volatilisation, such as the heavier petroleum tar and shale oils, is that the method of distillation used should as far as possible avoid this cracking action. Lastly, it is desirable that the results of the laboratory fractionation of an oil should give results which approach as nearly as possible to those which will be obtained when the oil is distilled on the large scale in a refinery.

The writer is accustomed to carry out the laboratory distillation tests on crude oils or tars in two operations, each performed in a special apparatus. In the first of these the oil is submitted to a topping distillation up to a temperature of 500° F. (260° C.), by means of which in the case of a crude petroleum oil the petrol, water, and kerosene are separated together. This preliminary topping distillation is carried out on a quantity of 1,000 cc. of the crude oil or tar, heated in a glass distillation flask of about 1,500 cc. capacity. During the whole of the distillation a current of 2.4 cubic feet of air per hour is sucked through the heated liquid by means of an electric motor-driven air-pump. The current of air and vapours of distillation products are cooled down after leaving the still by passing through a water-cooled condenser; this separates the condensible vapours, and the air containing only traces of vapour is then once more heated, and passed through the hot oil, and thus continuously circulates until the distillation is complete. The vacuum in the distillation flask throughout this operation is about eight inches of water.

The second stage in the fractionation of the crude oil is next carried out on the residue left in the flask after the topping has been completed. For this purpose it is convenient to use a still of small capacity for laboratory tests. The still which the author has devised has been found to give satisfactory results when dealing with not more than 700 to 800 cc. of the topped oil.

CALORIFIC VALUE OF MOTOR-SPIRIT.

It is not desired to raise a discussion on all the details of the fractionation of motor-spirit at the present moment. The many varieties of test in use are generally so well known that it appears useless to describe or criticise them further, until it is possible to do so under the auspices of some authoritative body charged with the duty of selecting and recommending a standard method of test for general adoption. There is, however, one point in the distillation tests of petrol, concerning which a remark must be made. The usual method of determining the initial distillation-point of motor-spirit is to record it as being the temperature at which the first drop of condensed spirit falls from the thermometer or other specified part of the distillation apparatus.

The determinations of the distillation-point by this method, and by all analogous methods with which the author is acquainted, lead to somewhat discordant results in tests made on the same sample by different observers, and, indeed, even in repeat tests by the same observer. The precise meaning of the figure obtained by such tests, even if it were always found to be the same for the same sample of spirit, cannot be readily defined; it is certainly not the boiling-point of the liquid, and it can only be considered as a very rough measure of the pressure which the spirit is likely to set up when stored in hermetically-closed containers at any temperature. For these reasons the author prefers to ascertain the temperature at which the vapour-pressure of the spirit is equal to that of the atmosphere. This can be very readily done by means of

what is known as the U-tube method of determining boiling-points.

DISTILLATION TESTS OF MOTOR-SPIRIT.

It is considered that the best method for determining the calorific value of motor-spirit of high calorific value in a bomb calorimeter is as follows:—

The liquid is weighed out into a small, stoppered, glass tube, or into a sealed glass bulb, such as are used in vapour-density determinations by Victor Meyer's method. The stoppered tube or sealed bulb containing the petrol is then placed on the platinum tray of the bomb in contact with a small weighed quantity (about 0.25 gramme) of pure naphthalene which has been previously fused, and the ignition-wire adjusted so as to permit of the electric ignition of the naphthalene after the bomb has been closed. On firing, the heat liberated by the combustion of the naphthalene blows out the stopper of the glass tube, or bursts the bulb, and the spirit is thus liberated and ignited without any possibility of loss occurring, a possibility which, as far as the author is aware, is very real in all other methods of burning such volatile liquids in a bomb calorimeter in the interval between weighing out the petrol and closing the bomb.

For heavier oils about one gramme is usually taken for calorimetric tests, and if for petrol, about 0.5 gramme is used with 0.25 gramme of naphthalene, the percentage-error of test is somewhat raised, but it is less than 0.6 per cent., which is quite satisfactory for all practical purposes.

In order to carry out the determination of the calorific value and of the water value in the same operation the following procedure is adopted:—

The fuel is weighed out (one gramme for solid fuel or heavy oil fuel, and for motor-spirit about 0.5 gramme in a glass-stoppered tube, together with 0.25 gramme of naphthalene). After placing the weighed fuel in the bomb and closing it, about a litre of oxygen gas is run through in a gentle stream, in order to remove the nitrogen present, and thus to reduce the formation of nitric acid to a minimum. The exit tube is then closed, and oxygen is admitted until the pressure rises to 30 atmospheres, when the determination of the calorific value is completed in the ordinary manner.

The exit-tube of the bomb is next connected to an absorption train, consisting of the following tubes connected in series: First, a small glass U-tube immersed in broken ice, where most of the water is deposited; second, a five-inch U-tube filled with pumice saturated with strong sulphuric acid in which the remainder of the water is absorbed; thirdly, three Mohr's potash bulbs connected in series, in which the CO₂ is absorbed; and lastly, a calcium-chloride guard tube. The exit tube of the bomb is then gradually opened, and the gas is run through the absorption-tubes at the rate of about two or three bubbles per second. When the gas ceases to flow, the entry tube of the bomb, which has been connected to the usual air purifying train to remove CO₂ and moisture, is opened, and air is sucked through, whilst the bomb is heated up to a temperature of about 250° F. by means of an air bath. The whole operation of determining both the calorific value and the water value of a fuel, and also, if desired, the amount of carbon and of sulphur contained by it, is about three hours, and very concordant results can be obtained even with the most volatile motor-spirits.

There are sources of special error in this method of combustion, which, if recognised, can be reduced to a minimum by suitable precautions. These are:—First, the possibility of the formation of nitric acid during the explosion in the bomb, which acid will later be absorbed with the water, and cause this result to be too high. The second source of error is due to the sulphuric acid formed by the combustion of any sulphur in the fuel. This acid will retain a certain proportion of water in the bomb when it is heated up to 250° F., whilst the stream of air is being passed through it.

WATER IN OILS, TARS, ETC.

When water is present in tars, and also to some extent in creosotes, trouble is not infrequently experienced in driving it off by means of bubbling a stream of dry air through it whilst heated to 212° F., for great frothing may occur. This frothing appears to be due to the fact that the bubbles of water in these liquids are sometimes very small, and therefore, as the extra pressure, above that of the external atmosphere, to which the water in the bubbles is exposed from the surface tension of the film enclosing them, is inversely proportional to their diameter, it may have a considerable magnitude, and prevent the water from giving off vapour until the temperature is well above that necessary to produce a vapour-pressure equal to that of the external atmosphere. When, however, the temperature finally rises sufficiently high to cause the water in the bubbles to commence to give off vapour, they increase in diameter, but this increase at once reduces the pressure due to surface-tension of the liquid envelopes of the bubbles, and hence their condition of equilibrium is unstable, and they expend very rapidly, causing the phenomenon known as frothing, which is especially marked if the number of bubbles of water present in the tar is great, and their diameter is small.

A method of avoiding trouble due to frothing, which has been found to be very satisfactory, is to mix the 200 grammes of tar, creosote, or oil taken for test with about an equal weight of sand or of pieces of dried pumice, fire-bick, or other porous material of about $\frac{1}{4}$ inch diameter. The dried porous material should be heated to a dull-red heat, and then stored, whilst still hot, in a stoppered bottle until required for use.

It is very convenient to employ a routine method for determining water in all oil fuels, creosotes, or tars, for it is not possible to be certain by inspection that a given oil, creosote, or tar will not cause trouble due to frothing. The author therefore makes it the practice to mix dried pumice with all such samples when tested for water, and it is found that this precaution avoids the delay required for making the repeat tests which are sometimes found to be necessary if frothing takes place. It is chiefly because pumice, sand, or fire-brick are difficult to clean out of glass flasks without breakage that a conical copper-sheet flask is recommended for use in these determinations.

FREE ACIDITY OF OIL FUELS.

The methods used by the author for determining free acidities are as follows:—

(1.) *Free acidity to alcohol*: If the oil is not very dark or thick, an amount of 50 grammes is weighed into a 10-ounce bottle, and to this 100 cc. of neutralised alcohol, together with a few drops of neutralised phenolphthalein solution, is added, and the mixture is titrated with a deci-normal solution of caustic soda, in quantities of not more than one-tenth of a cc. at a time, the mixture being

well shaken after each addition, and then allowed to settle. The additions are continued until the separated alcohol just turns pink.

In the case of thick or dark-coloured oils, a quantity of 50 grammes of the sample is weighed into a 300 cc. glass flask, and an amount of 150 cc. of neutral alcohol added. The flask, covered with a watch glass, is heated on the top of a water-bath, but the alcohol should not quite boil. When hot, the mixture is well shaken up, and it will be found that the alcohol will then rapidly separate from the oil, and will be sufficiently clear within from 10 to 15 minutes to permit of its titration with deci-normal soda, using phenolphthalein as an indicator. The oil is again well shaken up after the addition of alkali, and once more heated and allowed to settle, and the titration repeated until a permanent pink colour appears. The whole operation may take as much as 6 or 7 hours to complete, but if it is attempted to carry it out in the cold, the periods required to separate the oil and alcohol will cause the test to take at least three times as long.

(2.) *Free acidity to water*: A quantity of 50 grammes of the oil is weighed into a 250 cc. separating funnel. A quantity of 100 cc. of distilled water, previously made just neutral to methyl orange is added. The mixture is then thoroughly shaken, allowed to settle and the separated water as far as possible run off into a beaker. This operation is again repeated with two further successive quantities of 50 cc. of neutralised water. The total washings are then mixed, and titrated with deci-normal caustic soda, using methyl orange as indicator. In the case of some very thick oils, separation of the water from the oil in the above operations is found to be inconveniently slow and tedious, and in such cases hot water is used, and if necessary, the whole separating funnel is heated by immersing in a hot-water bath.

EFFECT OF MOISTURE IN MINERAL OILS UPON THEIR FLASH-POINTS.

It is well recognised that the presence of moisture in an oil will cause its flash-point to vary in some way, but, as far as the author is aware, the nature of this variation and its amount is not known, or has not been recorded, whilst the connection between varying amounts of water present in a given oil and its flash-point, and the effect of the presence of a given quantity of water in oils of higher and lower viscosity and flash-point (observed in the dry state), and also in oils of different chemical character, such as petroleum oils, creosote oils, shale-oils, etc., has not it is believed been investigated hitherto.

The experiments which the author has carried out on this question appear to show that the most marked effect due to the presence of water in an oil having a flash-point above 150° F. is that it causes much greater variations in the results of a series of repeat flash-point tests made by a series of independent observers all testing the same sample of oil than are found when a similar dry oil is tested in the same way. If the oil containing water has a flash-point (when dry) of above 212° F. the variations between the results of repeat flash-point tests obtained by different observers are more marked than is the case if the oil has a flash-point less than 212° F. The variation between repeat flash-point tests on an oil containing water is, in fact, generally less the lower the flash-point of the oil.

TUNGSTEN ORDER SUSPENDED.—The Ministry of Munitions announces that the tungsten and Molybdenite Order, 1917, is suspended from October 18.

GOLD-ZINC-CYANIDE.*

BY W. R. FELDTMANN.

A DOUBLE cyanide of gold and zinc, which has, apparently, not hitherto been recorded, can be produced in two forms:—

(1) When solutions of, respectively, one equivalent of ZnCl_2 and two equivalents of KAuCy_2 are mixed and allowed to stand for some hours, crystals deposit which, although minute, are easily identified under a low-power microscope as hexagonal prisms. These are nearly colourless, with just a perceptible greenish tinge. They form slowly in dilute solutions—*e.g.*, from a mixed solution carrying $\frac{1}{4}\%$ of KAuCy_2 , crystals commenced to separate in half an hour, but continued to deposit for at least two days.

Similar crystals are obtained by adding HCl to a cold cyanide solution containing gold and zinc in the proportions above indicated, until the solution is just acid to methyl orange. Except for the resulting presence of free HCy , this amounts to the same thing as adding ZnCl_2 solution to KAuCy_2 solution. For KAuCy_2 is a neutral salt, and it has been found that K_2ZnCy_4 , in dilute solution, requires four equivalents of HCl to neutralise it, so that the point at which methyl orange shows commencing acidity is the point at which all free cyanide has been decomposed and the K_2ZnCy_4 has been converted to ZnCl_2 ($\text{K}_2\text{ZnCy}_4 + 4\text{HCl} = 2\text{KCl} + \text{ZnCl}_2 + 4\text{HCy}$).

(2) If a solution containing two equivalents KAuCy_2 is mixed with two equivalents KC_y , and then with four equivalents of HCl , heated to boiling point and allowed to cool, and if a solution of one equivalent of ZnCl_2 is then added and the mixture allowed to stand for some hours, a slow separation of crystals again takes place. But the compound produced by this method is found to be composed of hexagonal pyramids or pyramidal combinations, in which the prism faces are absent. These crystals, also, are nearly colourless, but, in bulk, have a perceptible grey or lavender tinge.

The same pyramidal crystals can be formed by adding to the acidified, heated, and recooled gold solution a cyanide solution containing zinc in the proportion indicated, provided that sufficient HCl is present to render the final mixture just acid to methyl orange. If too little acid has been added, insoluble octahedra separate, carrying an appreciable amount of gold.

If, before the pyramidal crystals have time to form in the mixed solutions described above, the solutions are heated to boiling point, no pyramidal crystals appear, but only hexagonal prisms—*i.e.*, the prismatic is apparently the more stable form of the compound.

Gold and zinc were separated and estimated gravimetrically (the cyanogen being arrived at by difference) in both the prismatic and the pyramidal forms of the gold-zinc-cyanide. The percentage composition was found to be the same in both cases, *viz.*, 69% gold and 11.4% zinc, corresponding sufficiently closely to the empirical formula Au_2ZnCy_4 , with 69.9% gold and 11.6% zinc. In their general chemical characteristics the two forms of the compound have not been found, so far as observed, to differ materially. Nevertheless, there is a difference in origin, a difference in crystal habit, and a consistent difference in such slight tinge of colour as the crystals show in bulk. Collectively, these points seem to

indicate that this is a case of isomerism, and not merely physical isomerism or allotropy, but chemical isomerism, possibly as between Au_2ZnCy_4 and ZnAu_2Cy_4 , with gold as the base in the prismatic form and zinc as the base in the pyramidal form.

The formation of the prismatic isomer may be expressed as:—

But the formation of the pyramidal isomer cannot be quite analogous, as ZnCl_2 is not acted on by HCy (on the contrary, ZnCy_2 is decomposed by HCl). The reaction of formation cannot therefore be:—

but may probably be correctly represented as the action of aurocyanhydric acid on ZnCl_2 , thus:—

It should be noted that the reaction is an incomplete one, but the exact reason for this has not been ascertained.

In water, cold or hot, both forms of crystals are insoluble. They are slowly soluble in strong solutions of alkaline cyanides. Cold HCl , even if fairly concentrated, attacks them only slowly, with separation of AuCy . They dissolve readily in cold solutions of the alkalis and in ammonia. If to the alkaline solution so formed HCl is slowly added, zinc hydrate is precipitated, which, on further addition of acid, redissolves. When sufficient HCl has been added to render the solution just acid to methyl orange, the zinc-gold compound separates again (slowly, if the solution was diluted considerably), but only in the prismatic form, whether the crystals dissolved were prisms or pyramids—*i.e.*, the reaction in this case is once more between ZnCl_2 and KAuCy_2 . Sodium sulphide decomposes both crystals with separation of zinc sulphide and formation of alkaline aurocyanide. The zinc sulphide retains just a trace of gold, which can easily be separated by treatment with dilute HCl and filtering, the zinc being reprecipitated in the filtrate. The sodium sulphide method of decomposition was found to be a convenient way of separating the metals for the purpose of analysing the zinc-gold compound. When digested with a strong solution of potassium or sodium carbonate, the crystals are decomposed with formation of zinc carbonate, the gold again going into solution as alkaline aurocyanide.

The crystals can be heated at considerably above the boiling point of water without undergoing any change. When the temperature is gradually increased they first lose cyanogen, and become blackened with separated carbon. On further heating they become bright again, with a brassy gold colour, without loss of crystal form. When the temperature approaches red heat a sudden change becomes apparent, a red glow passes through the mass, the colour changes to a bronzy hue, and the crystals are then found to have fritted and lost their form.

TIN MINE ACCIDENT.—At the Levant tin mine, near Penzance, on Monday night, an engine collapsed while over 100 men were descending a shaft. A *Times* correspondent says the accident is the most serious which has occurred in the history of the industry. It is not yet known how many men were killed, but some estimates put it as high as 40. This is probably an exaggeration, but up to Tuesday evening nineteen bodies had been brought to the surface, and there were still sixteen men to be accounted for. A number of miners in different levels could not be reached, and until the shaft is cleared it will not be known definitely how many lives have been lost.

BRITISH OVERSEAS CHEMICAL TRADE IN 1918.

(Continued from page 418.)

WE give below extracts from the annual statement just issued, of the trade of the United Kingdom with foreign countries and British Possessions in 1918, compiled by the Customs and Excise Department. The figures relating to the chemical and allied trades will be found much more useful than those given in the monthly Board of Trade returns, owing to the detailed analysis of the countries of origin of imported, and the destinations of exported, chemical products. Each product is specified separately, together with the extent of the trade done with the more important countries, the corresponding figures for 1917 being in parentheses.

EXPORTS.

Aluminous Sulphates (including Alum).—Norway, 9,151 cwt. (25,288 cwt.); France, 115,845 cwt. (17,473 cwt.); Portugal, 10,142cwt. (7,353cwt.); Spain, 2,437 cwt. (6,615cwt.); Turkey, 120cwt. (80cwt.); United States, 728cwt. (5,294cwt.); Argentine Republic, 9,514 cwt. (23,723cwt.); other foreign countries, 32,778cwt. (70,386cwt.); Egypt, 28,484cwt. (19,317cwt.); Bombay, 2,931cwt. (47,824cwt.); Madras, 448cwt. (2,226cwt.); Bengal, Assam, Bihar and Orissa, 39,833cwt. (36,010 cwt.); Burmah, 338cwt. (628cwt.); Canada, 14,798cwt. (12,712cwt.); other British Possessions, 15,223cwt. (26,671cwt.); total, 282,770cwt. (301,600cwt.).

Arsenic and Its Oxides.—France, 1,581cwt. (1,049cwt.); Brazil, 2,569cwt. (1,577cwt.); Argentine Republic, 1,254cwt. (413cwt.); other foreign countries, 398cwt. (2,514cwt.); British Possessions, 408cwt. (1,016cwt.); total, 6,210cwt. (6,569cwt.).

Bleaching Powder.—Russia, — (1,000cwt.); Norway, — (9,200cwt.); France, 31,172cwt. (827cwt.); Portugal, 300cwt. (—); Brazil, — (82 cwt.); other foreign countries, 605cwt. (1,203cwt.); British India, 37,791cwt. (40,911cwt.); Canada, — (816cwt.); other British Possessions, 1,463cwt. (4,381cwt.); total, 71,331 cwt. (58,420).

Carbide of Calcium.—Foreign countries, 655cwt. (689cwt.); British Possessions, 995cwt. (976cwt.); total, 1,650cwt. (1,665cwt.).

Carbonate of Ammonia.—Russia, — (2,069cwt.); Netherlands, — (240cwt.); France, 633cwt. (4,575 cwt.); Italy, 5,122cwt. (4,973cwt.); Japan, 1,051cwt. (6,926cwt.); United States, — (1,755cwt.); other foreign countries, 1,674cwt. (6,259cwt.); British Possessions, 7,827cwt. (8,393cwt.); total, 96,307cwt. (35,190cwt.).

Coal Products, not Dyes.—Russia, — (£387,635.); Sweden, £2,003. (£5,502.); Norway, £44,696. (£134,369.); Netherlands, £75,347. (£41,484.); France, £1,494,261. (£1,533,402.); Spain, £156,522. (£25,433.); Italy, £397,624. (£426,014.); United States, £164,182. (£208,380.); China, £3,386. (£3,005.); Argentine Republic, £14,271. (£2,017.); other foreign countries, £389,445. (£201,065.); Egypt, £24,739. (£15,185.); South Africa, £30,299. (£51,998.); British East Indies, £45,118. (£62,141.); Australia, £5,624. (£7,781.); Canada, £10,260. (£3,318.); other British Possessions, £25,319 (£22,247.); total, £2,883,096. (£3,130,976.).

Copper Sulphate.—Russia, — (1,651 tons); Netherlands, — (1 ton); France, 41,073 tons (39,402

tons); Algeria, 3,516 tons (3,643 tons); Switzerland, 497 tons (106 tons); Portugal, 1,566 tons (1,469 tons); Spain, — (3 tons); Italy, — (66 tons); Greece, 589 tons (—); other foreign countries, 112 tons (95 tons); Egypt, 81 tons (39 tons); British South Africa, 59 tons (94 tons); Australia, 62 tons (386 tons); Canada, — (19 tons); other British Possessions, 41 tons (156 tons); total, 47,596 tons (47,130 tons).

Cyanide of Potassium or Sodium.—Dutch East Indies, 4,090cwt. (3,679cwt.); France, 8,132cwt. (4,133cwt.); Portuguese East Africa, 203cwt. (1,616cwt.); Spain, 2,447cwt. (1,429cwt.); Japan, 24,269cwt. (15,868cwt.); United States, 1,838cwt. (3,296cwt.); Mexico, 31,620cwt. (19,942cwt.); San Salvador, 5,296cwt. (4,149cwt.); Brazil, 3,240cwt. (4,787cwt.); other foreign countries, 7,042cwt. (12,141cwt.); Cape of Good Hope, 1,391cwt. (3,274cwt.); Natal, 8cwt. (4cwt.); Transvaal, 58,394cwt. (81,161cwt.); British India, 9,346cwt. (8,327cwt.); Australia, 19,671cwt. (24,182cwt.); New Zealand, 6,684 cwt. (6,215cwt.); Canada, 16,310cwt. (20,237cwt.); other British Possessions, 14,185cwt. (20,992cwt.); total, 214,166cwt. (235,432cwt.).

Disinfectants, Insecticides, Weed Killers, and Sheep and Cattle Dressings (except Tobacco Offal).—France, 13,900cwt. (13,466cwt.); Portuguese East Africa, 6,864 cwt. (7,359cwt.); United States, 6,395cwt. (6,572cwt.); Chili, 15,564cwt. (6,877cwt.); Brazil, 8,468cwt. (8,986 cwt.); Uruguay, 6,029cwt. (3,661cwt.); Argentine Republic, 98,043cwt. (91,863cwt.); other foreign countries, 17,907cwt. (15,816cwt.); Cape of Good Hope, 32,480cwt. (34,315cwt.); Natal, 14,252cwt. (13,796cwt.); Transvaal, 9,556cwt. (7,463cwt.); British East Indies, 39,645cwt. (43,960cwt.); Australia, 32,177cwt. (29,876 cwt.); New Zealand, 27,775cwt. (32,057cwt.); Canada, 2,151cwt. (2,364cwt.); other British Possessions, 12,540 cwt. (12,958cwt.); total, 343,746cwt. (331,369cwt.).

Dyestuffs, Products of Coal Tar.—Russia, — (1,889cwt., valued £50,971.); France, 6,850cwt., £95,942. (2,478cwt., £50,531.); Switzerland, 25,879cwt., £275,847. (26,466cwt., £214,549.); Spain, 2,237cwt., £36,357. (115cwt., £3,837.); Italy, 3,790cwt., £73,875. (4,775cwt., £94,493.); Japan, 238cwt., £9,100. (50cwt., £648.); United States, 8,198cwt., £137,966. (9,120cwt., £144,851.); Brazil, 2,477cwt., £68,084. (1,285cwt., £33,190.); other foreign countries, 1,789cwt., £32,497. (909cwt., £18,013.); Egypt, 2,642cwt., £55,204. (1,624 cwt., £14,973.); Bombay (including Karachi), 18,319cwt., £268,334. (15,571cwt., £307,941.); Madras, 2,818cwt., £18,846. (856cwt., £19,637.); Bengal, Assam, Bihar and Orissa, 1,168cwt., £21,750. (849cwt., £23,676.); Burmah, 13cwt., £667. (3cwt., £124.); Australia, 3,131cwt., £95,556. (2,287cwt., £63,979.); New Zealand, 372cwt., £8,046. (258cwt., £7,009); Canada, 3,686cwt., £45,755. (5,481cwt., £80,500.); other British Possessions, 305cwt., £7,833. (174cwt., £3,177.); total, 83,912cwt., £1,251,659. (74,190cwt., £1,132,099.).

Dyestuffs, Other Sorts.—Russia, — (16,906cwt., £60,913.); Sweden, 1,040cwt., £4,062. (2,855cwt., £5,750.); Norway, 37cwt., £381. (1,769cwt., £3,555.); Netherlands, — (171cwt., £743.); France, 4,541cwt., £34,974. (3,054cwt., £17,440.); Portugal, 555cwt., £3,220. (1,585cwt., £4,264.); Spain, 136cwt., £2,461. (404cwt., £4,026.); Italy, 1,372cwt., £12,040. (2,144cwt., £13,924.); United States, 4,627cwt., £13,891. (5,404cwt., £24,719.); Brazil, 242cwt., £3,200. (253cwt., £2,246.); other foreign countries, 3,939cwt., £29,692. (7,228cwt.,

£36,518.); British India, 727cwt., £8,097. (3,246cwt., £25,498.); Australia, 1,810cwt., £19,970. (8,405cwt., £45,862.); Canada, 411cwt., £1,412. (1,376cwt., £12,043.); other British Possessions, 1,258cwt., £11,137 (7,793cwt., £22,247.); total, 20,695cwt., £144,537. (62,593cwt., £279,748.).

Glycerine, Crude.—Cape of Good Hope, 17,341cwt. (32,913cwt.); other British Possessions, 3cwt. (—); total, 17,344cwt. (32,913cwt.).

Glycerine, Distilled.—Italy, — (10,298cwt.); other foreign countries, — (103cwt.); Cape of Good Hope, 15cwt. (20cwt.); Natal, 22,206cwt. (27,311cwt.); Transvaal, 21,445cwt. (27,769cwt.); Canada, — (1cwt.); other British Possessions, 118cwt. (110cwt.); total, 43,784cwt. (65,612cwt.).

Hydrochloric Acid.—Foreign countries, 297cwt. (461cwt.); British Possessions, 1,011cwt. (2,651cwt.); total, 1,308cwt. (3,112cwt.).

(To be continued.)

STANDARDISATION OF MINERAL OIL TESTS.

IN the course of a very lengthy paper before the Institution of Petroleum Technologists on Tuesday, Mr. Arnold Philip, chief chemist to the Admiralty, at Portsmouth, dealt in great detail with the question of laboratory tests on mineral oils. The central fact which was brought out by the paper was the necessity for standardisation of mineral oil tests with a view to removing the constant disputes which take place between suppliers of oil and the large users owing to the different methods of testing which are adopted. The immediate question arising out of the paper is whether or not a Standardisation Committee should be appointed. The suggestion has been dormant for two years, but there is undoubtedly a great deal of support for putting it into effect now. Consequently, the general feeling of the meeting seemed to be rather against discussing the details of standardisation, but to leave that as the work for the committee, if, and when, appointed.

Sir Thomas Holland, who is home on leave from India, where he has done so much good work as Chief of the Indian Munitions Board, made a long and interesting speech on the subject. There were several difficulties to get over in connection with standardisation, he said. First of all, there was the British character; but if we postponed standardisation there would undoubtedly arise further vested interests which would make it more difficult. At the same time, it was not only the members of the Institution who would be affected by standardisation. It would be necessary to work with other bodies, especially the chemical societies, which had already done a considerable amount of work in this direction. There was also the question of international co-operation to be thought of. Nevertheless, we in this country should not postpone acting until we had got other countries acting in full co-operation, and it would not do to act precipitately without inviting the advice and assistance of other countries, especially America. Even before a committee was formed there were other things to be thought of. One was the question of money. It would not be possible to set up standards without work, and they would not get work done without being paid for. The Engineering Standards Association spent considerable sums every year, and a portion of the work of the

proposed committee would touch the work of the Engineering Standards Association, especially in connection with lubricating oils. It would therefore be necessary to consider the question of who was to meet the bill, and whether it should be done by private effort or whether it was fairly chargeable to Government funds. The first thing they should do was to form a preliminary committee whose work should be to gather together what had already been done in the direction of standardisation and indicate lines of further action. He felt that that would be better than at once forming a Standardisation Committee.

Dr. Dunstan expressed the hope that if and when a Standardisation Committee had been formed it would include within its purview some of the more recent fuel oils, such as cannell oils, low-temperature tar oils, and lignites, which undoubtedly had an important future in this country.

Professor J. S. S. Brame agreed that the question of money was the first and most important consideration. He agreed with Sir Thomas Holland that we must not be too insular in this matter of standardisation. There must be co-operation with other societies and with other countries. After all was said and done, we were not producing petroleum in very large quantities in this country at the present time, and England was not entitled to rank as a first-class oil producer. Whilst we should take our share in arriving at standardisation, he would point out that there were companies which had a big oil production in other parts of the world. It was most important to co-operate with America, who already had gone a considerable distance in the direction of standardisation. There had been some very excellent work carried out at the Bureau of Mines, Washington. It was no use chemists in this country, whether it was Mr. Arnold Philip in his laboratory at Portsmouth or a chemist in any other place, setting up their own arrangements, which worked very satisfactorily from their own point of view, without taking into consideration other facts, such as the work which had been done in the United States. He thought that they should consider how the Institution could inaugurate some scheme of standardisation, and also how they could get into touch with other countries. Flash-point and viscosity had already been dealt with by the International Congress of Applied Chemistry, and they should move warily and in co-operation with other people who had already been working on the question.

Dr. W. R. Ormandy expressed the opinion that there would be great difficulties to contend with in the future as the use of mixed fuels increased. Our tropical dependencies were coming forward with alcohol and alcohol-ether (natalite) fuels. In Australia a plant was being put down to make 2,000,000 gallons of this fuel per annum, whilst in India large plants were being installed. Therefore the question of the behaviour of these fuels would have to be studied, and methods worked out. We should also be faced with a new series of difficulties in regard to alcohol in its potable form, and that pointed to the necessity for the Institution taking action jointly with a view to standardise methods, which were required now and would be required more than ever in the future.

Mr. Philip, in a brief reply to the discussion, said he was prepared to scrap any method he had devised if, in the view of a Standardisation Committee, better methods existed.

DISCOLOURATION OF SULPHATE OF AMMONIA.

THE causes of the discolouration of sulphate of ammonia during the process of manufacture form the subject of an article in the current number of the *Times Engineering Supplement*.

In Germany, it is said, A. Thau has recently brought forward some more or less novel points, and states in particular that blue sulphate is far more common when the salt is produced by the ordinary distillation process than when it is obtained by "direct" means. The latter process, in fact, appears to overcome the formation of highly-coloured cyanides in the saturator. Prussian blue, which is the chief source of the trouble, is not decomposed by the action of acids, and the effect is greatly aggravated owing to the fact that in the matter of discolouration a very little goes a very long way. If, as is generally supposed, the Prussian blue is formed by interaction of volatile cyanides with the sulphide of iron invariably present in the sulphuric acid, then violent agitation (to avoid the formation of local neutral zones) should be sufficient to prevent the trouble. Thau has found, however, that even under such conditions, whereby local alkalinity is completely avoided, the blue salt is still obtained—particularly after just starting-up. He concludes, therefore, that "patchiness" in the saturator is not the primary cause, and alludes to the fact that dark blue condensates are frequently found in the connections between the still and the saturator. This would seem to indicate that the Prussian blue is formed before the saturator is reached, particularly as during the dismantling of plant, the surfaces of the still column and the delivery pipes are usually found to be coated with a very thin layer of the blue.

In advancing a new theory in connection with the subject Thau expresses the opinion that in the upper portions of the still and in the connections the iron is coated with ferrous sulphide which has been formed by the sulphuretted hydrogen distilled off from the ammoniacal liquor, and this reacts with the hydrocyanic acid obtained from the same source. Thus cyanide of iron is formed in the first place, and in the presence of oxygen and steam this is readily oxidised to ferric ferrocyanide.

In order that iron sulphide may be formed in the first instance as explained above, a certain concentration of sulphuretted hydrogen in the vapour is necessary, and if this concentration can be prevented or reduced there is every likelihood that the trouble will be stopped. The explanation probably depends upon the law of mass action; or an increase in the proportion of water vapour present may lead to condensation on the inner surfaces of the connecting pipes, which acts as a protection and prevents the sulphuretted hydrogen from attacking the metal. It seems likely, too, that whereas the objectionable reaction is assisted by lower temperatures, it is retarded by a higher temperature, for the use of a greater quantity of steam than is customary has been shown to be followed by relief from the trouble. Whether oxidation of the cyanide of iron takes place in the delivery pipes, in the saturator, or not until the sulphate or ammonia reaches the store, the ultimate effect is the same; but the whole matter is complicated by the fact that the blue colouring usually does not show itself until the salt has been lying for some little time in the store, this place being the most favourable for the process of oxidation. The amount of steam employed can best be

controlled by taking samples from the delivery pipe just before it enters the saturator, and it should be borne in mind that if attempts are made to avoid local alkalinity by reducing the steam the effect will be to assist the formation of Prussian blue.

In suggesting precautions which should be taken Thau states that when shutting down the stills the flow of liquor should first be stopped before the steam is turned off. The latter then effects a scavenging action, expelling the sulphuretted hydrogen from the whole system and thus precluding the formation of iron sulphide. In the same manner, the still should be well steamed before the plant is put to work again. Another means of prevention which has been tried is that of coating the interior of delivery pipes with lead, but the success is only partial, for even then the iron of the still-head is exposed to the vapours. In any case, however, the precaution should be taken to insert a siphon box at the point where the iron delivery pipe meets the saturator, the condensate from this being run back into the still. As regards the employment of higher temperatures it may be mentioned that pre-heating of the ammonia liquor, though a self-evident point, materially assists in maintaining the desired temperature in the still-head. It assists, moreover, in rendering the concentration of water vapour higher in the delivery pipe, thus reducing the formation of sulphide of iron. In conclusion, it should be borne in mind that the presence of hydrocyanic acid and sulphuretted hydrogen is not of very material importance so long as the action of these compounds on the iron portions of the plant is prevented.

SCOTTISH OIL PROSPECTS.

AT a meeting of the Mining Institute of Scotland, on Saturday last, a paper on "Scottish Oil Possibilities" was communicated by Mr. H. M. Cadell, F.R.S.E. Mr. R. McLaren, M.P., president of the Institute, occupied the chair.

The author said that the whole of the strata from the Broxburn shale down to the old red sandstone, a depth of some 4,000 feet, were already well known to geologists, and the supposed oil sand must be somewhere in the section. But on examining every likely bed, such as the Binny sandstone, Burdiehouse limestone, Hailes, Craigleith, and Granton sandstones, no signs of an oil sand nor indications of extensive reservoirs of oil or oil gas could be detected. The oil was known to occur along anticlines or arches in the strata, and a boring had been started some months ago, so far without success, to find oil near West Calder on an anticline in the shalefield there. Another boring was projected for oil on the Roman Camp Hill in Mid-Lothian, where a larger anticline was known to occur. But in both cases the strata were traversed by numerous faults, and consequently any oil that might be found would probably be small in quantity in each borehole. It was thus extremely unlikely that much, if any, liquid petroleum would ever be got either in the Lothians or anywhere else, and in thousands of bores that had already been made in Scotland no oil of any importance had ever been found. The author was regretfully forced to that conclusion by the mass of existing evidence, but he said he did not wish to end with an altogether pessimistic note, as there was still an untapped source of oil he would like to refer to.

UTILISATION OF PEAT.

The peat mosses were said to be larger than the coal-fields, and recent investigations had shown that the deep black peat in some large bogs was, when once the water was eliminated, richer in oil and ammonia than the best oil shales. The dry peat in some cases could be made to yield more than 26 gallons of oil and 100lb. of sulphate of ammonia per ton, and one large bog in Mid-Lothian had enough nitrogen to produce 180lb. on a practical scale, which was worth 22s. 6d. for that product alone, with the oil and other products of distillation in addition. The peat, if dry, was thus worth about three times the value of ordinary shale, that had up till now been workable at a small profit. The difficulty was eliminating the 80 to 90 per cent. of water in the peat before it could be distilled for oil and ammonia. But this was a new and a large source of oil and might appropriately be investigated, as it had great possibilities and would be very advantageous as an industry, especially in many of the poorer districts.

In the course of the discussion Dr. Flett, of the Geological Survey, reported that the West Calder bore was now down to a depth of 900 feet, but at the bore in the vicinity of Dalkeith there would be some little delay before drilling could be commenced. The situation of the Scottish bores had been most carefully selected, and he could state from personal knowledge that steps were being taken to procure perfectly definite opinions on this important, although highly disputatious subject. Within a comparatively short period the results would be to hand, and if the wells did not yield oil then, in view of the strong opinions of Scottish geologists, it was not at all unlikely that the question would be regarded as finally settled.

The Chairman said he did not know what the cost of these boring operations in the Lothians would be. If the bores, however, did not turn out satisfactorily, as appeared to be foreshadowed by Scottish experts, then the House of Commons and the public would assuredly have something to say.

Mr. Cadell, replying to the discussion, said he felt it was a great mistake on the part of the Government, especially in England, to lay down new bores before they had ascertained the definite results from any single bore that had as yet pierced the ground. It was, he feared, a serious waste of public money. No one would be more pleased than himself to see the Scottish bores successful, but the geological evidence was entirely against the presence of oil there.

OIL SHALE RESERVES.

According to estimates prepared by the Geological Survey, there are still very large reserves in the oil-shale fields of Scotland. In making the calculations, only beds of more than 3ft. in thickness have been reckoned, and no greater depth than 300 fathoms is included. The average yield of crude oil per ton is taken at 25 gallons. Rich shales produce 60 to 70 gallons, and shales yielding as little as 19 may pay, because of the quantity of sulphate of ammonia they also supply. The "proved" and "probable" fields are estimated as containing 601,886,000 tons. Deducting 120,000,000 tons for shales that have already been worked, there remains an available reserve of 481,886,000 tons, a supply for 133 years at the present rate of working.

There are also 883,791,000 tons of "possible" reserves—that is to say, areas where there are few or no bore-holes, but where geological considerations point

to the presence of shales of workable thickness and quality within 300 fathoms of the surface. Should these actualise, the reserves they contain would increase the duration at the present rate of working to 383 years. Subject to the cost of wages not becoming prohibitive and the prices of oil, paraffin wax, and sulphate of ammonia being maintained at reasonable figures, there is an assured future for this industry in Scotland.

NEWS FROM THE ANTIPODES.

(FROM OUR OWN CORRESPONDENT.)

SYDNEY, September 1.

Importation of Sheep Dip.—In reply to a question in the Senate, the Vice-President of the Executive Council, Senator Russell, said the quantity of sheep dip at present held up by the Customs authorities was 1,650 five-gallon drums, 1,324 one-gallon drums, and 900 cases. The Minister added that at the time the shipments were made the exporters were aware of the proclamation prohibiting the importation of sheep dip into the Commonwealth unless with the consent of the Minister of Customs. Being prohibited imports, the goods were liable to forfeiture, but as a special concession the Government had agreed to allow shipments made since the issue of the proclamation to be held under Customs control pending the introduction of the new tariff. Delivery could then be given subject to payment of duty.

Wallaroo-Mount Lyell Fertilisers.—For the twelve months ended June 30 the report of the Wallaroo-Mount Lyell Fertilisers shows a gross profit of £47,432., against £41,725. for the previous year, after providing for depreciation. Administration expenses amounted to £14,779., and after transferring £4,375 to appropriation account, the net return is £28,278. Adding £74. brought forward, the sum available is £28,352. A dividend at the rate of 8 per cent. absorbs £26,952., of which half was paid in April, and the balance of £1,400. is carried forward. The report states that great difficulties have been experienced in maintaining the supplies of raw material, and this condition is likely to continue for some time, owing to the shortage of shipping.

Price of White Lead.—The Sydney market price for Australian genuine ground white lead was recently advanced to £73. per ton, in lwt. packages, with the usual extras for smaller sizes. This represents a rise of £3. per ton.

Chemical Market.—Industrial chemicals were subject to moderate inquiry yesterday in the general merchandise markets. Quotations for the great majority of lines remained under indent cost, and merchants and manufacturers, therefore, filled their requirements from spot stocks. A parcel of powdered borax sold at £50. net per ton. Boracic acid has offered between houses at £85. net per ton. A quantity of liquid silicate of soda was placed at £21., less discount. Brunner-Mond's bicarbonate of soda was offering in 1½cwt. kegs at £15. net, but American was to be had at a lower rate. American 76-77 per cent. caustic soda had sellers at £23., and English, 70-72 per cent., at £22. 10s. per ton. Caustic soda, 98 per cent., was scarce, and commanding £50. Acids attracted rather more attention than of late, although actual sales were not numerous. Cream of tartar, in parcel lots, showed slight improvement, holders asking 2s. 9d. net per lb. for French, 95 per cent., and 2s. 7½d. net for American, 99 per cent. English or Italian tartaric acid was available in merchant parcels at 3s. net, and citric acid at 3s. 3d. net. Sellers of turpentine in quantities withdrew from the market. Those who had stocks preferred to keep them for their distributing trade. The nominal rate for parcels was about 13s. net per gallon, but small lots were offered at 10s. 6d. for ordinary trade business. Linseed oil was firmly controlled, the best prices for distributing lots being 9s. 6d. and 9s. 8d. per gallon respectively for raw and boiled. White lead was steady at £70 to £86 per ton basis, according to make.

Zinc and Zinc Dust Prices.—The price of Australian high-grade zinc-dust (88-92% metallic zinc) remains at £70. per ton, c.i.f. U.K. The price of Australian electrolytic zinc, containing 99.95% metallic zinc, is unchanged at £42. per ton, f.o.b. Australia for direct shipment to New Zealand, India, South Africa and the Far East.

ITEMS OF INTEREST.

WEST AUSTRALIAN COPPER.—*Reuter's* correspondent at Perth, West Australia, in a message dated October 18, states that the Inspector of Mines reports hopefully on the copper find discovered recently in a range between Peak Hill and Nullagine.

CHEMICAL WORKS' STUDENTS.—The Salters' Institute of Industrial Chemistry has awarded grants in aid to thirty young persons occupied in chemical factories in or near London to assist them in improving their knowledge of chemistry.

BUSINESS NOTICE.—We understand that the entire share capital of the firm of Kiloh and Co., Ltd., wholesale and retail chemists, Cork, has just been acquired by the Cork Chemical and Drug Co., Ltd., the purchase price amounting to a considerable sum.

ACID DRUM EXPLOSION.—While a drum used for storing acid was being dried on a fire in Devonport Dockyard on Tuesday it exploded, killing an apprentice named Clement. William Warren, chargeman of fitters, was injured badly, and others received minor injuries.

JOHN KNIGHT, LTD., AND LEVER'S.—A statement has been made by the chairman and managing director of Messrs. John Knight, Ltd., categorically denying certain rumours which have been circulated regarding the possibility of the absorption of the company by Messrs. Lever Brothers, Ltd.

PLANS PASSED.—Plans were recently submitted to the Aberdeen civic authorities by the proprietors of the Sandilands Chemical Works (Messrs. John Miller and Co.) for permission to erect a new superphosphate store in connection with their works. The plans were in order, and permission to proceed with the scheme was granted.

FIRE.—A serious fire occurred on October 16 at the oil mills in Burlington Street, Liverpool, owned by Messrs. Earle and King, an associated firm of Lever Brothers. The fire broke out on the upper floor, which, with its contents, was almost totally destroyed, but the outbreak was confined to that floor, and was extinguished in about two and a half hours. Damage amounting to several thousand pounds was done.

ROTHAMSTED EXPERIMENTAL STATION.—The new laboratories at the Rothamsted Experimental Station, Harpenden, were opened on Monday by Sir A. Griffith-Boscawen, M.P., Parliamentary Secretary to the Board of Agriculture. The buildings contain a complete library and laboratories devoted to physics, protozoology, entomology, and mycology, the latter two being used in the new institute of plant pathology. Professor H. E. Armstrong (Vice-Chairman of the Lawes Agriculture Trust), presided.

NEW SCOTTISH COMPANY.—It is announced that a new Scottish limited liability concern has been established, under the name of Messrs. John Scott and Watson, to acquire and amalgamate the existing businesses of the Kildust Company, 178, Berkeley Street, and of the Phoenix Chemical Works, 61, Pollok Street, Glasgow. This company is a private one, and among the first subscribers are Mr. John Scott and Mr. Robert P. Watson, both of whom are well-known personalities in the West of Scotland chemical trade.

BRITISH-GROWN SUGAR.—In a letter to the British Sugar Beet Growers' Society, Lord Lee of Fareham has expressed his desire to ensure a complete and trustworthy test of the commercial possibilities of the growth of sugar beet and the manufacture of sugar therefrom in England. The society proposes to carry out the project at Kelham, near Newark, the management to be in the hands of the public shareholders and certain matters of financial policy to be controlled by financial representatives of the Government. The best expert information is being secured, and when formalities have been completed the scheme will be published in detail.

BOILER EXPLOSION.—Two men were killed and two others severely burned as the result of a boiler explosion last week at the ammonia works belonging to Messrs. William Baird and Co. Limited, Muirkirk, Scotland. It appears that a number of men employed by Messrs. Dick, Kerr and Co. Limited engineers, Kilmarnock, with John Mair, foreman blacksmith, were testing a boiler, when the latter burst, killing Mair instantaneously. John Kelly (44), foreman, was so severely injured that he died in the ammonia house. John Willock (28), riveter, and Alexander M'Dill, apprentice riveter, were also severely burned on the head and body.

FIXATION OF ATMOSPHERIC NITROGEN.—The board of the British Cyanides Co., Ltd., announce that the experiments on the fixation of atmospheric nitrogen, upon which large sums were expended prior to the war, and which were necessarily suspended during the war, have now been resumed. These experiments will take many months to develop, but the special furnaces which have been erected have already satisfactorily overcome some of the chief difficulties which the company before the war were endeavouring to solve.

CHEMICAL WORKS FATALITY.—The inquest has been held at the Huddersfield Royal Infirmary on Isaac Brown, a labourer, who was killed by an explosion of a pan at the works of Messrs. L. B. Holliday and Company, dye makers, of Deighton, near Huddersfield. Evidence was given that the pan had a steam jacket, with neither water gauge or safety valve. Mr. E. W. Norris (the Coroner) said that probably the danger was not realised either by the workmen or the management. It was for the management to devise some means for preventing such an occurrence in the future. In the circumstances, however, he would return a verdict of "accidental death."

DYESTUFFS SCARCITY.—The Batley and Birstall (Yorks.) Chamber of Commerce Council have passed a resolution urging the Board of Trade to take steps to secure without further delay an adequate supply of such dyewares as are essential to the woollen and many other British industries. The resolution says: "The meeting understands that manufacturers in France have already secured very large quantities of these dyes from Germany, and the same is true of Italy and Belgium. This meeting fails to see why the industries of this country should be hampered by lack of dyes while the needs of the Continental competitors are being fully met. Local manufacturers and buyers have already supplied to the Board of Trade, through the Colour Users' Association, lists of the dyes required for their businesses, and unless the dyes can be promptly supplied, and at reasonable prices, the export trade of the district cannot fully be regained."

CHEMICAL WORKERS' WAGES: ARBITRATION COURT'S AWARD.—The award was issued on Saturday last of the arbitration on the claim made for workers in the drug and fine chemical industry for the reduction of the working week to 44 hours, payment for overtime at the rate of time and a half, and minimum rates of wages varying from 65s. to 60s. a week for males and 45s. to 37s. 6d. for females. The Court have decided that the claim for reduction of the working week, and the payment of the minimum rates is not established. Adult male employees whose rates of wages do not exceed 15s. above the minimum set out in the claim for their respective grades, are to receive an advance of 5s. a week, and those whose wages exceed 15s. above the minimum are to have such an advance as will give them rates not exceeding 20s. above the existing minimum for the respective grades. Having regard to certain negotiations the claim for women is referred back, the parties to be at liberty to apply to the Court for a decision in the event of no satisfactory settlement being arrived at. No change is ordered in the payment for overtime. Claims for payment of 20s. to departmental foremen, and 10s. to deputy foremen above the minimum of each class, are held not to have been established.

NON-FERROUS MINING.—The Committee appointed by the Board of Trade to consider the question of non-ferrous mining met on October 14, 15, and 16, under the chairmanship of Mr. H. D. Betterton, M.P., when evidence was given by Mr. C. A. Moreing, M.Inst.C.E. (of the firm of Bewick, Moreing and Co.), general manager of the Tohidy Minerals, Ltd., and East Pool and Agar, Ltd., and representing the Cornish Chamber of Mines and the Joint Industrial Council of the Tin Mining Industry in the United Kingdom. Mr. Moreing stated that, in his opinion, the mines on the Redruth and Camborne line of lodes should be amalgamated and worked on a large scale, a plan which held out the only hope of economic success in the future. He pointed out the real importance of the mining industry of Cornwall not only to those actually employed in the mines and the population dependent on them, but also to the country at large. This week the Committee heard further evidence from Cornwall. Mr. Josiah Paull, manager of the South Crofty mine, in the Camborne and Redruth Central Mining District, giving evidence before the Committee stated that unless the price of tin moved in the same ratio to the price of labour and material State aid in some form was necessary to save the tin-mining industry in Cornwall.

LEGAL INTELLIGENCE.

T.N.T. Factory Explosion and Fire Insurance: Court of Appeal Decision.

The case of the Hooley Hill Rubber and Chemical Company v. the Royal Insurance Company, Limited, and others came before the Court of Appeal, consisting of Lords Justices Bankes, Scrutton, and Duke, on Friday, October 17, upon the appeal of the plaintiff company from a judgment of Mr. Justice Bailhache in the Commercial Court. The case came before the learned judge upon a special case stated by Mr. Langdon, K.C., as arbitrator, and the question raised arose out of a fire insurance policy on the premises of the plaintiffs. Two points arose for decision: (1) Whether a clause in a fire policy which excepted damage caused by explosion applied so as to exempt the insurance company from liability where the explosion was only incidental to and in the course of the fire; (2) assuming that the first point was decided against the plaintiffs, whether the insurance company was estopped from putting that construction upon the policy when it had induced the plaintiffs to refrain from insuring against explosion loss by making a representation in writing that the exception did not include such a risk.

The plaintiff company, which manufactured T.N.T., carried on business at Ashton-under-Lyne on premises it had built for that purpose. The company was insured under policies issued by the Royal Insurance Company and other companies.

Condition 3 of the policy of the Royal Insurance Company provided as follows: "This policy does not cover . . . loss or damage occasioned by or in consequence of invasion, foreign enemy, rebellion, insurrection, riot, civil commotion, or any military or usurped power whatsoever, earthquake, volcano, or subterranean fire, loss or damage by explosion, except loss or damage caused by explosion of illuminating gas elsewhere than on premises in which gas is manufactured or stored." The other companies' policies contained a similar condition. Upon the Royal Insurance Company's policy the following memorandum was typewritten: "This policy does not cover loss or damage by explosion nor loss or damage by fire following an explosion where it be proved that such a fire was not caused directly or indirectly thereby or was not the result thereof."

On June 13, 1917, a fire broke out in the works of the plaintiffs. It burnt fiercely for 20 minutes, and did great damage. Later an explosion took place which shattered the premises. A quantity of T.N.T. in closed receptacles was exposed to the intense heat of the conflagration, and this caused the explosion. The loss suffered by the assured up to the time of the explosion was assessed by the arbitrator at £12,740. The loss suffered by the assured through the fire and the explosion together amounted to a sum far in excess of the aggregate amount of the sums insured under the policies which had been issued to the assured by the insurance companies. It was admitted by the insurance companies that they were liable to indemnify the assured for the loss suffered by them through the fire, but they contended that they were not liable under the policies for the loss which followed the explosion, on the ground that the conditions of the policies exempted them from that liability.

It was contended on behalf of the assured that they were entitled under the policies to be indemnified not only for the loss caused by the fire, but also for the loss caused by the explosion, on the ground that the explosion was an incident in the course of the fire, and that the proximate cause of the whole loss was the fire.

The arbitrator found, on the authority of *Stanley v. Western Insurance Company*, that the contention of the insurance companies was well founded, and that the contention of the assured could not prevail. Mr. Justice Bailhache upheld the finding of the arbitrator, and affirmed his award on both points, and from this decision the plaintiff company now appealed.

Mr. Douglas Hogg, K.C., for the appellants, said the appeal raised two points: first, as to the effect of an exception in a fire policy of an explosion risk, and, secondly, if, contrary to the appellant's contention, that point was decided against them, whether one of the respondent companies—viz., the Royal—was not estopped from setting up the effect which they sought to give to that exception.

The hearing was adjourned until Monday.

At the conclusion of the arguments, their lordships on Monday held that the decision which Mr. Justice Bailhache followed in the case of *Stanley v. Western Insurance Com-*

pany, which had been unchallenged for some 50 years, and presumably acted upon in insurance matters, was correct, and they dismissed the appeal upon the main point raised as to construction. It was, however, directed that a further question affecting the Royal Insurance Company as to whether that company was estopped from relying on the true meaning of the policies legally construed by reason of certain operations by the agent of the Royal in two letters during the negotiation of the policies should stand over for a week, and to be then argued unless the parties in the meantime could come to an agreement.

The China Clay Corporation: Receiver Appointed.

In the Chancery Division on Friday of last week, before Mr. Justice Sargant, Mr. Galbraith, K.C., moved, on behalf of Mr. H. Mallaby-Deeley, M.P., one of the trustees of a debenture trust deed securing the stock of the China Clay Corporation, Limited, for the appointment of a receiver and manager of the assets of the company. Counsel said the other trustee was Sir Charles Augustus Hanson, and he and the plaintiff were also directors, and Sir Charles was a defendant in the action.

The company was incorporated in 1910 with a capital of £400,000., of which £270,000. had been issued for the purpose of acquiring certain china clay lands in Devonshire, including leasehold properties, subject to a rent of £500. a year. In 1914 the company issued or raised £20,000. on the security of first mortgage debenture stock, and the trust deed was executed, the effect of which was that the company covenanted to pay 6 per cent. interest and to pay off the stock by yearly payments of £2,000. The company by the deed also specifically mortgaged the freehold and leasehold properties, and gave a floating charge on all its assets.

The plaintiff now held the whole of that £20,000. issue. No interest was ever paid on the first debenture stock, and in July, 1916, a supplemental trust deed was entered into, which recited that the debenture stockholders had agreed to the further issue of £20,000. to rank *pari passu* with the first issue, and it provided that the interest on the £40,000. accruing before June, 1916, and the termination of the war should be paid out of the profits only. In all, £34,460. stock was issued, and, in addition, £5,000. stock was issued to the directors of the company, of which Mr. Mallaby-Deeley held £833., to secure an overdraft.

The company had got into difficulties, £500. was due for rent, and in August, 1919, the company, owing to its financial difficulties, had practically to close its operations, though steps had been taken to keep the premises open, the company having sold 3,000 tons of clay, the sale of which in normal times would take 30 weeks to complete. In these circumstances the company passed a resolution that for the protection of the interests of the company Mr. Mallaby-Deeley should be asked to start proceedings for the security of the debenture holder, he being the holder of £20,838. stock.

Counsel for the company and for Sir Charles Hanson assented to the motion, and his Lordship appointed a receiver and manager of the assets of the company.

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Bisbee Tin Smelting and Arsenic Company, Ltd.—Resolved September 19, confirmed October 6: That the company be wound up. R. B. Petre, 11, Ironmonger Lane, E.C., chartered accountant, liquidator. Meeting of creditors, W. B. Peet and Co.'s, 11, Ironmonger Lane, E.C., October 21.

Isle of Wight Cement Works, Ltd.—Resolved October 3: That the company be wound up. R. E. Crane, 8, Paternoster Row, E.C., incorporated accountant, liquidator. Meeting of creditors at liquidator's, October 22.

DISSOLUTIONS OF PARTNERSHIP.

(Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.)

Viking Packing Company, The (Joseph Harding and Geo. Jenkins), 5, Richard Terrace, Cardiff, self-raising flour and soap-powder merchants. September 8. Debts by G. Jenkins. (October 10.)

BRITISH ASSOCIATION OF CHEMISTS.

"If we don't hang together we shall assuredly all hang separately."
—JOHN HANCOCK, when signing the Declaration of Independence.

Hon. Registrar: DR. FRANCIS W. KAY,
Chemical Department, The University,
Liverpool.

NOTICES.

Reprints of the Proceedings.

It was decided at the last Council meeting that the Proceedings of the Association should in future be issued once a month, and that reprints from the *Chemical Trade Journal* and *Chemical Engineer* should be distributed to members free of charge, so as to ensure that all members are kept informed of the doings of the Association. It has not yet been decided what steps shall be taken in the case of those members who have already paid 4s. to have the reprints sent them for one year, but they will certainly be compensated. The Proceedings were at first issued fortnightly, but during the summer months the sections had little to report, and the number of issues was curtailed. The Council meets monthly, and a copy of the proceedings will in future be issued as soon after the Council meeting as possible.

THE PROCEEDINGS OF THE ASSOCIATION.

The Council.

The 25th Council meeting, postponed from September 27 on account of the railway strike, was held at Derby on Saturday, October 11, Professor Hinchley being in the chair.

Income-tax Rebate.—The President reported that Mr. Millington (London) and Mr. Zeally had been appointed by the London Committee as a special sub-committee to deal with this question. They will report to the London Section Committee, which will then report to the Council. As previously reported, it is proposed to approach the Income-tax Commissioners with a view to obtaining rebate on the necessary professional expenses of chemists.

Guarantee Fund.—The President reported that liberal responses were coming in freely to the letter which was circulated to members appealing for support to the Guarantee Fund. The Association is incurring considerable expense in connection with the propaganda campaign, and although the financial position is sound, it will strengthen the hands of the officers of the Association to know that they have such a fund behind them.

Assistant Secretary.—Of a number of applicants who had replied to the Association's advertisement for an assistant secretary, three were interviewed by the Council, and of these Mr. Alan Stewart Mills was chosen, and was appointed for a trial period of six months. This appointment of an assistant secretary was a very necessary step, and will relieve the voluntary officers of a great deal of clerical work, for which they could ill spare the time.

Special Brigade R.E. Chemists.—Correspondence was considered dealing with the retention in the Army of chemists of the Special Brigade R.E. in subordinate non-technical work. It was decided that the president should prepare a summary of the facts, and place them before a member of Parliament for inquiry in the House of Commons.

Accounts.—The Hon. Treasurer's report, showing income, expenditure, and balance-sheet from December 1, 1918, to August 31, 1919—audited and found correct by Messrs. Sibbald Stones and Co., chartered accountants, of Derby,—was accepted. The finances of the Association were shown to be in a satisfactory condition. Dr. Hedley submitted a number of recommendations made by the auditors for controlling the financial affairs of the Association. It is absolutely necessary that local sections should submit monthly statements and monthly claims, if any, to the hon. treasurer.

Nominations Committee.—On the recommendation of the Nominations Committee, 74 candidates were elected as full members, nine as probationers, and two as students. Whilst twenty-four candidates, approved by the local assessors, were declared elected as full members, and seven as probationers, subject to the final approval of the Nominations Committee. One candidate, previously elected probationer, was, on account of a fuller and sufficient statement of his qualifications having been received, recommended to the Nominations Committee for election to full membership.

Whitley Councils Committee.—Mr. W. E. Kay reported the results of a conference of scientific and technical associations held in London on September 6, at which the B.A.C. was represented by the president, Mr. Millington, Mr. Holton, and himself. He stated that the conference accepted the whole of the proposals made by the B.A.C. representatives, and that at the close Professor Hinchley, on behalf of the Association, had intimated adherence to the Federation subject to the confirmation of the Council. It was resolved that the action of the representatives be approved, and that the president, Mr. Garland, and two of the three following members from the North—viz., Mr. Kay, Mr. Millington, and Mr. Holton—attend the Federation meeting to be held in London on October 18 as the B.A.C. delegates.

Draft Rules.—The rules, as amended, incorporating the suggestions made by the various sections, were submitted, and the committee were instructed to distribute copies to the local section committees for their final approval.

Munitions Chemists: Widnes Election.—The publication as propaganda of the questions submitted to the candidates in the Widnes by-election, and the answers received, was discussed; and on the motion of Dr. Kay, seconded by Dr. Hedley, it was decided first to submit the matter to the section committees for consideration, with a view to the preparation and adoption of a political programme as a permanent element in the B.A.C. organisation.

Leeds Section.—At the request of the Leeds Section for help in connection with a special meeting to be held there, Professor Hinchley, Dr. Hedley, and Dr. Foster undertook to attend and speak.

Salaries.—The attention of the Council having been drawn to an advertisement in the *Gas World* for a gas works chemist at a salary of £200., including war bonus, the President read a strongly worded letter (referred to elsewhere) protesting against the absurd inadequacy of the salary offered.

Reprints of the Proceedings.—On the motion of Mr. Kay, seconded by Dr. Forster, it was resolved that the editorial matter in the *Chemical Trade Journal* and *Chemical Engineer* appear only once a month, and that the reprints (together with other matter if desired) be issued periodically, without charge, to all members, probationers, and students.

Next Meeting.—The next meeting of the Council will immediately precede the annual general meeting, which will be held in Manchester on Saturday, November 15.

CHEMISTS AT £200. A YEAR.

The Council is indebted to Dr. E. W. Smith, chief chemist of the City of Birmingham Gas Department, for calling attention to the following advertisement, which appeared in the *Gas World* of September 6 last, under the heading, "Situations Vacant":—

"Works Chemist wanted for a 500-million works in the North of England. Applications preferred who have had College and works training, the latter extending over six or seven years. Duties shall include all usual laboratory and works tests, qualitative and quantitative analysis. Salary £200. per annum, including war bonus. Apply, stating age, experience, qualifications, etc., to Box 3130, *Gas World* Offices, 8, Bouverie Street, E.C. 4."

Dr. Smith himself wrote a strong protest to the anonymous advertiser, of which he was good enough to send us a copy; and the following letter was also sent, signed by the president, on behalf of the B.A.C.:—

Dear Sir,—Our attention has been drawn to your advertisement in the *Gas World* of September 6, 1919, in which you advertise for a fully qualified chemist at a salary of £200. per annum.

We wish to suggest most emphatically to you that such a salary is a disgraceful salary to offer a highly educated man with six or seven years' works experience; and it is quite impossible you will obtain a suitable man, unless you take advantage of his poverty through the circumstances of the time. The salaries paid to chemists under pre-war conditions indicated the backwardness of chemical industry in this country, but the salary you offer, if compared on a rational basis, is very much lower than the pre-war salary of the type of man you want.

The salary for the kind of man you require should be at least £350. per annum, and we can assure you that the payment of such a salary will mean, as far as you are concerned, a much greater benefit than £350. per year would indicate; and if you are wise in your own interests you will not think of any lower salary.

Finally, we may state that it is our intention to fight such people as yourselves not only in the personal interests of chemists, but in the interest of the country itself.—Yours faithfully,

For and on behalf of the Council,
J. W. HINCHLEY, Chairman.

Further comment on this case is needless. In taking up such cases as this the B.A.C. is fulfilling one of the functions for which it was formed, and members should not hesitate to call the attention of the Council to any such cases with which they may become acquainted.

FEDERATION AND WHITLEY COUNCILS.

The definite formation of the Federation of Scientific and Technical Professional Associations, as reported in the above proceedings, furnishes a convenient occasion for shortly summarising the part played by the B.A.C. towards bringing this about.

Early in the present year the Council of the B.A.C., alive to the possibilities of service to the industries of the country inherent to the Whitley scheme, but largely lying dormant and unappreciated, appointed a Committee to promote the representation on Whitley Councils of the chemist and the technician as a necessary complement to the employer and the manual worker, who so far had monopolised representation on these bodies.

This Whitley Committee in the first instance secured the services of Mr. Todd of the Ministry of Labour to address the Association on the subject, and 5,000 copies of this address were printed for general circulation.

The B.A.C. Whitley Committee however, recognised at the outset that little progress would be made if the combined forces of those who furnish the scientific and technical experience to industry were not brought into play, and it lies to their credit that they were the first to bring together the various scientific and technical organisations round a common table to discuss in concert the furtherance of the movement.

It is unnecessary to dwell upon the vicissitudes of these conferences, the difficulties that arose, and the cross purposes that were engendered; it is sufficient to say that the spirit of goodwill that animated them surmounted all obstacles; and, in justice to the B.A.C. Whitley Committee, to add that the principles elaborated by them have been substantially adopted by the Federation that has been formed, and have furnished the basis of its constitution. These may be broadly summarised as follows:—

(1) That the activities of the Federation shall initially be confined to Whitley Council and like work.

(2) That to facilitate acceptance by the Board of Trade the constituent Associations shall be registered trade unions.

(3) That representation shall be claimed, distinct from that of the employer and the manual worker, as a third party furnishing to the common pool the scientific brain and the technical skill without which the two other elements are of no avail.

(4) That the independence and initiative of the constituent associations shall be in no way prejudiced or impaired, subject to the provision that they keep the Federation informed of any procedure that relates to movements that are the accepted objects of federal action.

(5) That group committees shall be formed within the Federation (e.g. chemists, engineers, etc.), that shall unify each professional interest, which otherwise would be spread over a variety of the constituent societies, representation being *pro rata* to the professional interest concerned.

(6) That the Federation shall be democratically controlled, and that its activities shall be determined by the voice of the members of its constituent societies, expressed through their representatives on the Federal Council. Thus, for example the addition of other fields of activity to that of Whitley Council work would be so determined.

Fourteen professional associations were represented at the conference last held, and seven of them have already joined the new federation.

DERBYSHIRE OIL OUTPUT.—It is officially estimated that 8,000,000 gallons of oil has steadily flowed at the Hardstoft Well, near Sheffield, since the heart of the stratum was first penetrated by the American borers. The flow has now attained an average of over 2,000 gallons per twenty-four hours. Drilling for the present has been temporarily suspended but will be resumed in the near future.

NEW COMPANIES.

Globe Oilfields, Ltd.—Capital £50,000., 10s. shares. Registered office: Finsbury Pavement House, E.C.

Research Association of British Rubber and Tyre Manufacturers.—Registered October 9. Objects: To promote research and other scientific work in connection with the rubber and tyre manufacturing and allied industries, etc. Solicitors: J. B. and F. Purchase, 14, Regent Street, S.W.

Anglo-Trinidad Petroleum Company, Ltd.—Private company. Capital £100., £1. shares. Registered office: 13, Copthall Court, E.C.

Crystal Manufacturing Company, Ltd.—Private company. Capital £2,000., £1. shares. Object: To take over the business of a vinegar brewer carried on by G. Pickup at Pipwellgate, Gateshead, as the "Crystal Vinegar Company." Registered office: 7A, Pipwellgate, Gateshead.

H. J. Enthoven and Sons, Ltd.—Private company. Capital £120,000., £100. shares (340 A preference, 460 B preference, 200 C preference, and 200 ordinary). Merchants, metal refiners, etc. Registered office: 70, Lombard Street, E.C.

Lead Wool Company (1919), Ltd.—Private company. Capital £30,000., £1. shares. Object: To take over the business of the Lead Wool Company, Ltd. (in liquidation), including certain licences for the United Kingdom and British Colonies and patent rights relating to metallic packing. Registered office: Churchfields, Snodland, Kent.

Matthew Marshall, Ltd.—Private company. Capital £10,000., £1. shares. Object: To take over the business lately carried on as tallow manufacturers, oil and explosive merchants, and powder agents at Gateshead, Newcastle-on-Tyne, and elsewhere. Registered office: Emerson Chambers, Blakett Street, Newcastle-on-Tyne.

Mica Manufacturing Company, Ltd.—Private company. Capital £25,000., £1. shares. Manufacturers, importers, exporters of and dealers in mica, micanite and insulating materials, paints, varnishes, papers and paper cloths, electric, magnetic, galvanic, chemical, and other machinery. Office: 22½, Cazenove Road, N. 16.

Morrison Silica Brick Company, Ltd.—Private company. Capital £10,000., £50. shares. Registered office: Ynisderw Road, Pontardawe, Glam.

New Silver Nitrate Company, Ltd.—Private company. Capital £2,000., £1. shares. Object: To take over from B. A. Chapman, Joan H. Daniel, and H. A. H. Spinney the business of manufacturers of nitrate of silver carried on by them in London. Registered office: 61-2, Chancery Lane, W.C.

Victoria Chemical Works, Ltd.—Private company. Capital £5,000., £1. shares. Manufacturing chemists and druggists, oil and colourmen, etc. Registered office: 85-88, Minories, E.C. 1.

Noflame Paint, Ltd.—Private company. Capital £6,000., £1. shares. Oil, varnish, and colour men, pharmaceutical, manufacturing, and general chemists, druggists, and dry-salters, etc. Registered office: 1, Quality Court, Chancery Court, Chancery Lane, W.C. 2.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

The continuance of the iron moulders' strike has retarded the improvement in the hematite pig-iron trade which had been expected to take place after the settlement of the railway strike, and the result is that only half the normal output of the 380 by-product coke ovens in this district is required for the ironworks in West Cumberland and North Lancashire. There will be no material change for the better until at least three additional furnaces on ordinary iron are relighted. Of this, however, there is a reasonable probability within two or three weeks. It is quite on the cards that two more furnaces may be in operation at Workington and one at Barrow, and in that event the output of the ovens would have to be increased by one-third. The East Coast coke supplies have not undergone any diminution, as there is no reduction in the number of furnaces on low phosphorus brands of iron, for which the harder coke is used. To West Cumberland this week they are 7,500 tons, and to the Furness district, 12,300 tons. The make of benzole and sulphate of ammonia is not now sufficient to meet demands, but there is more pitch and creosote than can be readily absorbed, and acids, of course, are very dull.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Nitrate of Soda.—Good progress has been made with sales by the Producers' Association in Chili, a further quantity of 170,000 tons being reported as disposed of for November shipment at 9s. 4d. per quintal, f.o.b., for ordinary quality, making about one million tons in all since the beginning of operations in September. Curiously enough, since nitrate was obtainable at the fountain-head at the above figure, considerable resales are said to have been effected at 9s. 5d. to 9s. 5½d. for 95 per cent., and at twopence per quintal more for 96 per cent. quality, the premium on the latter having been judiciously reduced since the disappearance of the buying for "munitions"; we have repeatedly stated that the Allies, represented by the Nitrate of Soda Executive in London, were made to "pay through the nose" for so-called refined nitrate prices altogether out of proportion to the extra cost of production. Encouraged by success, the Producers' Association, primarily established for the purpose of "fixing" prices, and thereby preventing fluctuations detrimental to the trade, has again raised its limits to 9s. 7d. for delivery up to December 15, and 9s. 9d. beyond that date up to June 30, 1920. The seller is, of course, entitled to ask his own price—the anti-profiteering Act does not extend to Chili,—but in the present case the ostensible *raison d'être* of the Association is obviously stultified by the successive advances from 9s. to 9s. 9d. per quintal within a few weeks the while the cost of production has tended downwards. The European farmer does not yet take any interest in the Chilean fertiliser for next spring; but some doubt seems to exist with regard to the source of supply of the hundreds of steamers and sailing-vessels required to move a million and a half tons of nitrate of soda from the West Coast within the next five months.

North African Phosphates' Fine Prospects.—The Ministry of Industrial Reconstruction recently called together the managers of the African phosphate companies to ask them to intensify their production during the current year. The mines, according to the latest report, promised to increase the tonnage in 1919 by about 150,000 tons, of which two-thirds would be reserved for French use. It is quite understood that for next year the African production will be greater than that of the current year, and it is hoped that the quantity to be reserved for France will enable the producers of superphosphates to acquire all the phosphates that they have already contracted for. French agriculture can, therefore, count on something like normal deliveries of superphosphates, provided always that transport facilities equal to their requirements are available. Tonnage is now plentiful, and enough to carry all that has been hitherto reserved for France; and it is hoped that the mine owners will be left free from official interference, so that they may meet their engagements.

New Italian Fertiliser Company.—The *Fabbrica Concimi Bosio Viadana di Calvisano* has been formed for the production of chemical fertilisers and sulphuric acid. The capital is 250,000 lire.

Sulphate of Ammonia.—Business in this material moves easily all the time, and it appears that the production is going rapidly into consumption. Some fears are being expressed in certain quarters about the possible future demand, but this seems groundless. Sulphate of ammonia is in increasing favour in this country, and there is a likelihood of the home consumption expanding year by year for some time yet. Higher prices may, of course, check demand somewhat, but it is not to be supposed that higher prices will prevail for a considerably prolonged period. A readjustment must come. Export trade continues quiet in view of all the circumstances. From across the Atlantic news comes that there are large orders for sulphate of ammonia there. The difficulty experienced is in locating supplies with the large producers. There is also good inquiry noted for material for the balance of the year, and, according to all reports, American producers are well booked up over this period. Little material is available in double bags for export. Lots that appear in the resale market from time to time create considerable buying interest, and holders are not obliged to make concessions to bring business to a head.

Superphosphate and Basic Slag.—These products remain in request, especially the milder and cheaper forms of basic slag. At the same time, although orders are still coming in, deliveries are very much behind, and it will take manufacturers some time to work off orders now on hand. Potassic-

super (carriage paid, 4-ton lots), 4 and 26 per cent., in bags, is quoted at £9. 1s. to £9. 2s. 6d. per ton.

Potash.—The expected new trade in potash manures does not seem to be working up so well as was expected. The various descriptions are not at all settled in market value. It is reported from one good source that the Government offers do not meet trade requirements to the extent that is to be desired. Although supplies are reported to be only of small extent, there is said to be an improvement. For the week ended October 18, the imports of Alsatian potash amounted to 1,185 tons of 14 per cent. sylvinit (French kainit). Current quotations for Alsatian potash salts are as follows: Sylvinit, 14 per cent. (French kainit), £7. per ton; 20 per cent., £8. 7s. 6d. per ton; muriate of potash, 80 per cent., £19. 7s. 6d. per ton.

Other Fertilisers.—Bone meal remains in short supply, and, if anything, the price is inclined to harden. East Indian is much wanted, and over £16. has been quoted at Liverpool. Pure steamed material, 1 per cent. ammonia and 60 per cent. phosphates, in bags, is £13. 10s. to £14. per ton, ex works. It is again stated that imports of nitrate of lime will be resumed next season, when it is hoped that difficulties concerned with the moisture absorption will prove to have been overcome by the production of nitrate of lime in a granular and dust-free condition.

Italian Notes.—The *Unione Concimi* of Milan has held its general meeting for the sixteenth working year, terminating on June 30. The profits are reported to have been 3,401,093 lire, against 5,707,540 lire in the preceding working year. In the report the directors congratulate themselves on having been the first house in the country to offer fertilisers at 20 per cent. below the Government fixed price. However, with an eye to business, the directorate adds that the effect of this cheap fertiliser will be to more than double the consumption, and will ultimately tend to the advantage of the company. The report observes, further, that the question of raw material is, of course, the bottom one. Pyrites exist in abundance in Italy, and the company are supplied therewith by the largest producer, the *Montecatini*. But still there remains the grave question of phosphates, and this has been settled in favour of Italy; for France, which appeared at one time desirous of creating a monopoly therein for herself in respect to Tunisian phosphates for the purpose of treating them there, has contracted to let Italy have 600,000 tons a year.

The fertiliser market is unchanged, and remains calm. Demand is fairly active, and the supply so far satisfactory. In sulphate of ammonia there are no offers, there being little stock available. Small parcels are being quoted at 130-135 lire per quintal. The basic slag situation is unchanged. France has granted permission for the transport of some potash, and some parcels are arriving from England at high prices but of low grade.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

There is much activity in the tinplate trade, and business still pours in from the Far Eastern markets. More mills are to be restarted in order to cope with the increased demand that has sprung up during the last four or five weeks. Manufacturers have some difficulty in getting good shipments owing to the continual strife among the dockmen at Swansea. It is no uncommon occurrence to have a sectional strike once or twice in a week, and these greatly interfere with the regular despatch that just now is so much needed.

The demand for all kinds of patent fuel is exceptionally strong and pressing. The labour disturbances at the docks impede exports, but nevertheless some good cargoes have gone during the week from Swansea, chiefly to Valencia, Rouen, St. Malo, St. Brieux, and Dieppe. One of 6,500 tons left for St. Nazaire. Manufacturers at Cardiff sent much of their makes to Calais, and those at Port Talbot despatched 2,949 tons to Santander, and smaller cargoes to Rouen. The Graigola Fuel Company, of Cardiff, has taken over 40 acres of land near the Port Talbot Docks for the purpose of erecting new fuel works which it is anticipated will have an output of 4,000 tons per day.

The copper works remain partially idle owing to the scarcity of ore. A parcel of 180 tons of copper matte arrived at Swansea from Avonmouth for the Mond Nickel Company, whose works at Clydach have become more active; and 41,573 bags of copper precipitate came into Port Talbot for the Rio Tinto Company's works there.

At all the works turning out fertilisers much activity prevails. There exists a heavy demand for basic slag.

EXPORTS OF CHEMICALS AND ALLIED PRODUCTS.

(Concluded from page 429.)

SOCIETY OF CHEMICAL INDUSTRY.

BIRMINGHAM AND MIDLAND SECTION.

AN excellent programme of lectures has been arranged for the winter season by the Birmingham and Midland Section of the Society of Chemical Industry. The session was opened on Thursday at the University of Birmingham, when Mr. E. C. Rossiter gave a paper on "Potash Production." On November 13 there will be a joint meeting with the members of the Birmingham Metallurgical Society, and at this a paper will be read by Mr. C. J. Brockbank, of Thorold, Ontario, on "Production of Artificial Abrasives in the Electric furnace." On December 11 Mr. J. O. Sullivan will speak on "The Influence of Temperature, Concentration, Duration of Mash and Slackness of Malt, on the Starch Products of the Extract of Malt." The subject of "Catalysis" will be discussed on February 12. Dr. Maxted (Walsall) will speak upon it from an industrial point of view; Mr. D. F. Twiss will refer to its application to vulcanisation; and Dr. Morrell will give his conclusions on catalysis applied to the oxidation of oils. The session will be wound up with a paper (on March 25) by Dr. A. Slator on "An Apparatus for Estimating CO₂," and with one on "Labour-saving Devices in Chemical Works" at a conference on April 22. The last-named meeting has been arranged by the Chemical Engineering Group.

DYE IMPORT LICENSING PETITION.—Readers who have forms of the petition to the Right Hon. D. Lloyd George, M.P., on the dyestuffs licensing question, which is being organised by the British Chemical Trade Association, are asked to return them forthwith to the offices of the Association, 80, Fenchurch Street, London, E.C. 3.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

October 13th to 18th (inclusive).

Continuous Treatment of Hydrocarbons with Liquid Sulphur Dioxide. Allgemeine Ges. für Chemische Industrie. 25,317.
 Neutralising Oils or Fats. Bloxum, A. G. (Arbini). 25,528.
 Extraction of Fat or Oil from Raw Materials. Bollmann, H. 25,213.
 Transfusion of Combustible Liquids. Brewster, A. O. French. 25,499.
 Treatment of Wood, etc., for Obtaining Cellulose and Artificial Resin, Asphalt, Lac, etc. Claessen, C. 25,502.
 Distillation of Coal, etc. Davidson, T. M.; Low Temperature Carbonisation, Ltd.; and Armstrong, H. L. 25,103.
 Distillation of Carbonaceous Substances. Davidson, T. M.; Low Temperature Carbonisation, Ltd.; and Armstrong, H. L. 25,104.
 Acetic Acid. Dreyfus, H. 25,479.
 Treatment of Petroleum, etc. Dunstan, A. E. 25,336.
 Pyroxylin Compositions. Du Pont de Nemours and Co., E. I. 25,494.
 Substitute for Horn, Vulcanite, etc. Fitzgerald, F. W. V. 25,139.
 Non-inflammable Compounds Containing Cellulose-collodion, Celluloid, etc. Fitzgerald, F. W. V. 25,140.
 Combinations of Pyramidal Surfaces for Purification of Liquids, Vapours, and Gases. Gaillet, P. H. A. 25,486.
 Utilising Differences of Fluid and Vapour Gravities. Hoare, R. R. 25,589.
 Sulphuric Acid Valves. Hodge, J. 24,977.
 Distillation and By-product Recovery of Waste Grease. Lane, L.; and Williams, D. H. 25,116.
 Crates or Holders for Carboys, etc. Leigh, H. 24,966.
 Concentrating or Washing Ores, etc. Lesser, M. 25,529.
 Lead Pigments. Mackay, P. A. 25,544 and 25,545.
 Recovering Vanadium from Its Ores. Mackay, P. A. 25,546.
 Lubricating Greases. MacLaurin, R. 24,956.
 Oxidation of Zinc, Tin, etc., and Production of Oxides of Such Metals. Maconochie, H.; and Ros, R. de. 25,405.
 Colloid or Colloidal Substance. Moseley, J. F.; and Williams, M. L. 25,355.
 Effecting Crystallisation from Solution. Norsk Hydro-Elektrisk Kveistofaktieselskab. 25,018.
 Evaporating Processes. Stead, J. C. 25,169.
 Degasification of Coal. Young, N. 25,276.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 6d. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.

1916.

Artificial Asphalt-limestone Zimmer. 11,331.

1917.

Titanium Compounds. Wrigley, H.; Spence, H.; and Spence and Sons, P. 14,950. **133,336**

1918.

Calcium Carbide. Beckett, F. M. 7,239 and 7,240.

Metal Alloy Containing Manganese. Stabilimenti Biak—Ing. A. Pouchain. 10,209. **133,354** and **133,355**

Metal Alloy. Stabilimenti Biak—Ing. A. Pouchain. 10,210. **133,362**

Basic Lead Sulphate. Wilson, S. B.; and Purex, Ltd. 10,978. **133,363**

Aluminium Alloy. Stabilimenti Biak—Ing. A. Pouchain. 11,947. **133,367**

Glycerol. Eoff, J. R. 11,948. **133,373**

Clarifying or Recovering Lubricating Oils. Helmes, M. J. 16,170. **133,374**

High-percentage Carbazole. Soc. d'Eclairage, Chauffage, et Force Motrice. 16,291. **133,415**

Making Combustible Gases from Carbonaceous Material. Palmer, C. S. 16,304. **121,455**

Treating Ore Concentrates, Fines, Slimes, Dust, and the Like. Reece, O. 16,325. **119,874**

Synthetic Production of Hydrogen Peroxide. Moritz, R. 16,376. **120,044**

Esters of N-mono-arylsulpho-mono-alkyl (allyl, aralkyl)-amido-oxy-aryl compounds N-mono-alkyl- (allyl, aralkyl)- amido-oxy-aryl compounds, and aryl-sulpho-esters of amido-oxy-aryl compounds. Imray, O. (Soc. of Chemical Industry in Basle) 16,379. **120,045**

Centrifugal Separation. Maues, W. 16,523. **133,433**

Utilising Residues from Bituminous Shales, Cannel Coals, and the Like. Broxburn Oil Co.; and Findlater, R. H. 16,542. **133,448**

Bituminous Material. Wade, H. (Barrett Co.). 16,847. **133,452**

Apparatus for Mixing Paints. Wilkinson, F. 16,955. **133,466**

Potassium Fluoride from Silicate Rocks. Dutt, E. E.; and Dutt, P. C. 17,081. **133,471**

Mineral Selective and Frothing Agent. Marks, E. C. R. (Luckenbach Processes, Inc.). 18,028. **133,474**

Low Temperature Carbonisation. Yeadon, J. A.; and Whitaker, T. 257. **133,498**

Metal Alloy Containing Manganese Stabilimenti Biak—Ing. A. Pouchain. 6,986. **133,554**

257. **133,605**

COMPLETE SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

1919.

Hydrogenation. Dayton Metal Products Co. 11,439. **133,666**

Liquid Fuel. U.S. Industrial Alcohol Co. 24,852. **133,709**

Resin-like Bodies. Melamid, M. 24,916 and 24,917. **133,712** and **133,713**

Sedimentation Apparatus. Dorr, C. O. 24,936. **133,716**

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Nitric Acid. K. B. Quinan, Somerset West, Cape Province, South Africa. British Patent, 131,029, of 1918.

The oxidation and absorption of gases containing nitric oxide is effected in apparatus having a number of permeable diaphragms upon which water is held in such a manner that the gas passes through the diaphragms but the liquid does not, suitably proportioned spaces being provided to allow of oxidation of the nitric oxide between successive contacts with the absorbent. Cooling devices may be provided for the absorbent and gas respectively at suitable points of their course. Fig. 1 shows an arrangement of plant comprising absorbers 2, 2^a - 2^d, oxidation chambers 4, 4^a, 4^b, 4^c, and the liquid tanks 5, 5^a - 5^d to receive the liquid from the absorbers through coolers 10, 10^a - 10^d, the liquid being returned to the absorbers by pumps 7, 7^a - 7^d. The course of the gas is

1, 2, 4, 2^a, 4^a, 2^b, 4^b, 2^c, 4^c, 2^d, while the liquid is supplied at 11 to the tank 5, and passes by overflow pipes 11^a - 11^d to the other tanks, and is withdrawn at 11^e. The construction of the absorbers is shown in Figs. 4 and 5, in which the gas enters at 16 and leaves at 17, while liquid enters at 14 and leaves at 15, so that the gas passes through the perforations in the plates 13 and (in Fig. 5) 13^a and through the layer of liquid upon these plates, the pressure of the gas, diameter of the perforations, and depth of liquid being so arranged that the liquid does not percolate through the plates. In the construction shown in Fig. 5, the liquid overflows from the plate 13 to a trap 18, from which it reaches the second plate 13^a. Means, such as blocks capable of being raised or lowered, may be provided to allow of closing down some of the perforations in the plates.

Ammonium Nitrate and Sodium Sulphate. C. W. Bailey, H. S. Denny, and A. T. Jefferis, H.M. Factory, Langwith, Nottinghamshire. British Patent, 131,017, of 1918.

Suitable proportions of ammonium sulphate and sodium nitrate interact in the presence of a bisulphate—for example, sodium bisulphate. Sodium sulphate separates from the hot solution and is removed. When the solution has cooled, without dilution, ammonium nitrate separates. Ammonium sulphate and sodium nitrate, in proper quantities, are added to the final solution, and the process is made continuous. Nitre-cake may be used as the source of the sodium bisulphate employed.

Acetaldehyde. J. Crosfield and Sons, Warrington; and T. P. Hilditch, Grappenhall, Cheshire. British Patent, 131,084, of 1918.

In the production of acetaldehyde by passing acetylene into acid solutions of mercuric salts, the mercury sludge formed in the process is revived by adding to the reaction liquid a small quantity of manganese dioxide, lead dioxide, red lead oxide, or cerium dioxide, and agitating the mixture by passage of gas or by mechanical agitation; the revivification is repeated until the solution ceases to be an effective absorbent. The reaction liquid should contain 0.5 to 1.5 per cent. of mercuric oxide, and the apparatus should be free from metallic parts; the lower portion of the apparatus should contain baffles to break up the gas current. An example is given of the use of manganese dioxide.

Chlorosulphonic Acid. Clayton Aniline Company, A. Schedler, and E. N. Marchant, Clayton, Manchester. British Patent, 131,024, of 1918.

Chlorosulphonic acid is prepared by passing hydrochloric acid gas obtained as a by-product in the chlorination of organic compounds—such as benzole, toluol, nitro-benzene, acetic acid, etc.—into sulphuric acid containing about 80 per cent SO_3 .

Ammonia and Hydrogen. E. B. Maxted, Walsall, Staffordshire. British Patent, 131,049, of 1918.

A mixture of nitrogen and hydrogen for the production of ammonia, or the hydrogen alone, is purified from carbon monoxide by preliminary passage over a base-metal catalyst, such as nickel or cobalt, at a temperature such as 350°C ., which is below that required for the production of ammonia, but sufficiently high for the production of methane. The gases are treated while under pressure, which may suitably be that required afterwards for the production of ammonia.

Phenol-formaldehyde Condensation Products. H. V. Potter and Damard Lacquer Company, Westminster. British Patent, 131,112, of 1918.

A purified condensation product of phenol (or cresols) with formaldehyde, free from uncombined phenol, is prepared by heating phenol (or cresols) with not more than an equal weight of formaldehyde solution (40 per cent.) in the presence of small quantities of an alkaline condensing-agent, such as ammonia, dissolving the viscous condensation product in aqueous caustic alkali and precipitating the pure condensation product by means of acid. The product, washed and dried, is a white amorphous non-resinous powder with a definite melting-point, and may be hardened by heating to an insoluble infusible product, or may be mixed with definite amounts of free phenol or resinous phenol-formaldehyde condensation products to give resins.

Lead Chloride. F. E. Elmore, Boxmoor, Hertfordshire. British Patent, 131,353, of 1918.

Lead zinc sulphide ores and concentrates are heated with sufficient strong hydrochloric acid to attack the lead but not the zinc, and the cooled residue is washed with cold water to remove acid and soluble impurities. Lead chloride is then recovered from the washed residue by hot water or brine, which is used alternately to dissolve the chloride and to deposit it in a cooling vat. The zinc sulphide of the ore remains unattacked. The lead chloride may be treated with sulphuric acid, which may be obtained from the sulphuretted hydrogen evolved in the ore treatment, and the hydrochloric acid obtained is then used again.

Dehydration of Tar. C. A. Klein, Brimsdown, Middlesex. British Patent, 131,087, of 1918.

This invention relates to the dehydration of tar, particularly that obtained from producer plants, and consists in bringing the watery tar into intimate contact with a convenient excess of water at a temperature above 40°C . The process may be carried out by forcing the heated tar through a perforated screen into a vessel containing water at a temperature above 40°C .; by causing a jet of steam to impinge on a jet of tar above the water vessel; by heating the tar in an excess of water by jets of live steam; or by violent mechanical agitation of the tar in the presence of an excess of water heated to a temperature above 40°C . The tar is finally allowed to settle, and is stated to contain less than 4 per cent. of water.

Estimating Vapours in Gases. H. S. Davis and M. D. Davis, Clifton, Nova Scotia. British Patent, 131,154, of 1918.

The amount of a vaporous constituent of a gas is measured by measuring the partial pressure due to the vapour in an apparatus comprising two similar flasks 1, 2, connected through a manometer 3, and having rods 6 passing through the stoppers, sealed by rubber tubes 8. Small sealed bulbs 10 containing the liquid or solid, corresponding with the vapour to be measured, are attached to the bottom of the rods, and are adapted to be broken against the bottom of the flasks by pressure on the rods. One of the flasks is filled with the gas to be analysed, and the other with air; the pressures are brought to atmospheric by momentarily opening cocks 11, and the bulbs 10 are broken. The pressure in one flask is increased by the full vapour pressure, while that in the other is increased by this amount less the pressure due to the

vapour already in the gas. The pressure difference shown on the manometer measures, therefore, the vapour pressure which existed in the gas. Solutions may be used in the bulbs 10. The sum of the vapour pressures due to more than one constituent of a gas may be measured by using a solution which evolves one of the vapours and dissolves the other vapours. The "light oil" vapours in coal gas may be measured by using benzene, or benzene and toluene, or benzene, toluene, and xylene in the bulbs 10. The flasks may be packed in melting ice, and solid benzene used in the bulbs.

Separating Tar Oils. R. Lessing, London. British Patent, 130,362, of 1918.

Tars and similar bodies are separated into oils and pitch by treatment with solvents which dissolve tar oils but not pitch, at a temperature above that at which the pitch is to be obtained melts. Preferably, the tar is first dehydrated, and the ammoniacal liquor, benzole, and naphtha are thus removed.

The solvent is a petroleum distillate, the bulk of which boils at a temperature above the melting point of the pitch—e.g., a petroleum spirit boiling at 100 – 120°C . The apparatus consists of a vessel A in which the tar and solvent, admitted by pipes 1, 2, are mixed by a stirrer a at a temperature of 100°C . maintained by a steam-coil 9. The solution of tar oils overflows by a pipe 4 to a packed tower or column still B heated by close steam. The solvent vapours are led to a condenser D, and the recovered solvent is led back to the vessel A. The tar oils and pitch are removed through outlets 6, 11. A plunger 10 is used to clear the solvent-admission pipe 2. The operation may be continuous or intermittent. To purify the tar oils the solution, on its way from the vessel A to the still B, is washed by a liquid, an alkaline liquid being used to remove phenols, etc., and an acid liquid to remove pyridine, etc.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Preventing Incrustation. Aktieselskapet de' Norske Saltwerke, Bergen, Norway. British Patent, 131,279. Convention date, August 14, 1918.

In evaporators for liquids containing calcium salts, to prevent the formation of calcium sulphate on the heating surfaces, crystals of calcium sulphate are suspended in the liquid to take up the sulphate separated by evaporation. The liquid is agitated during evaporation to prevent the crystals from settling. The crystals may be formed by gradually pouring lime water into the boiling liquid.

Fractional Distillation. E. A. R. Chenard, Cognac, Charente, France. British Patent, 130,092. Convention date, August 5, 1918.

In fractional distillation, the vapours from a still 1 are passed upwards through a series of elements consisting of concentric tubes 4, 5 through which a reflux obtained by condensation flows downwards. The arrangement is such that an exchange of heat takes place between the vapours surrounding the tubes 5 and the liquid within the tubes 5 while the vapours and liquids are flowing in the same direction. The reflux is obtained by passing the vapours through a series of separators 7 each consisting of cones, Fig. 2, in which the

vapours expand, and which are provided with filtering-boxes 10 packed with inert material to separate the particles of liquid formed during the expansion. The resulting liquids flow by pipes 11 to the zig-zag pipe 6, by which the vapours are led from the elements 4, 5 to the separators 7. Certain impurities may be removed by means of a pipe 12 communicating with one of the pipes 11.

Nitric Acid. F. Gros and Bouchardy, Paris. British Patent, 131,336. Convention date, June 16, 1917.

In the production of nitric acid of about 98-100 per cent. strength from liquid nitrogen peroxide, oxygen, and water or aqueous nitric acid, the nitrogen peroxide is employed in such excess as to maintain the liquid saturated throughout the operation—that is, the ratio of nitrogen peroxide to water is at least 15 : 1. The action of the oxygen is continued until the lower layer consists of nitric acid of 98-100 per cent. strength containing nitrogen peroxide and the upper of nitrogen peroxide containing a little nitric acid of the same strength. The oxygen may be employed under pressure—for instance, 20 atmospheres, —and a somewhat raised temperature not above 30° C. may be used. The mixture is agitated during the reaction. The operation may be effected intermittently or continuously. In the former case, the two layers which form may be separated, and the nitric acid layer may be distilled to recover the excess of nitrogen peroxide; while the other layer, which is mostly nitrogen peroxide, may be used again, or the whole mixture may be distilled together. In the latter case water, liquid nitrogen peroxide, and oxygen are introduced at B, C, and A respectively in the necessary proportions. The product flows out through S, and the excess of oxygen carrying nitrogen peroxide escapes at F. By heating the lower part E to 50-60° C. the peroxide is expelled from the acid, and is condensed by cooling the part G.

Recovering Solvents. E. I. du Pont de Nemours Powder Company, Wilmington, U.S.A. British Patent, 131,273. Convention date, August 8, 1918.

Volatile solvents are recovered from coated surfaces, such as split hides and aeroplane wings, by passing a current of air over the surface and passing the vapour-laden air through

an absorbent consisting of "dead oil"—i.e., a coal-tar distillate boiling at 240—350° C. This absorbent is particularly applicable for recovering vapours of ethyl, propyl, butyl, and amyl acetates. The recovered solvent is afterwards separated

from the absorbent by distillation, effected preferably by blowing air or steam through the heated liquid. The coated surfaces are run on a truck 5 into a drying-chamber 1 heated by a steam coil 2. Solvent-laden air is withdrawn through outlets 10, 11, and is led by a pipe 12 to a cooler 13, and thence to an absorbing-tower 18, in which it is passed repeatedly through a counter-current of an absorbent liquid. The vapour-free air is withdrawn through a pipe 23 by a pump 24, and may be returned to the drying-chamber by the openings 3, normally used for inspection purposes. The wheels of the truck 5 run between rails 7. The coating-table 8^b may have hinged sides 8^c, which are used to prevent heavy vapours from streaming down to the floor. As the coating proceeds, the truck is gradually pushed into the drying-chamber, air being meanwhile sucked into the chamber through the door 4. A dope used for coating aeroplane wings consists of nitrocellulose dissolved in a mixture of butyl acetate, benzole, and ethyl acetate.

PARLIAMENTARY NEWS.

Contract for German Potash.

In the House of Commons on Wednesday, Sir A. Geddes, replying to Mr. Chadwick, said: Contracts for material needed by the Government have been placed abroad by the Board of Trade, since the Armistice to date, only in respect of timber and potash. With regard to potash, one contract has been entered into with the German Government, representing an amount of £750,000. In each case the contracts were entered into in order to secure necessary supplies of the commodities in question for the United Kingdom. The potash contract also provided a means whereby the German Government might pay for a portion of their imports of food. With regard to contracts entered into by Departments other than the Board of Trade, I would refer my hon. friend to the Ministers responsible for the contracting Departments concerned.

Import Restrictions.

Sir A. Geddes, invited by Mr. Kiley to state the articles in respect of which import restrictions continue, and on what grounds they were imposed, said the general object of the restrictions was explained by the Prime Minister in his statement on trade policy just before the Recess.

Oil Royalties.

Mr. Holmes asked the Prime Minister whether the Government had come to a decision concerning the payment of royalties on the oil discovered in Derbyshire.

Mr. Bonar Law: Yes, sir; the Government have come to the decision that no royalty should be payable in the case of oil.

Railway Rates.

In reply to questions, Sir E. Geddes said that no general revision of railway goods rates had been, or could be, made until the Rates Advisory Committee to be set up under Section 21 of the Ministry of Transport Act had been appointed. He hoped the list of those appointments would be made in the next few days, and that the Committee would be asked as their first task to advise upon a scheme for the immediate increase of freight rates.

REPORTS OF COMPANIES.

A. and F. Pears, Ltd.

The meeting was held in London on Tuesday, the Right Hon. Lord Dewar (the chairman) presiding. The Chairman, in moving the adoption of the report, said: Our customary dividends and interest to debenture and preferred shareholders have been paid; the preferred ordinary shareholders receive 12 per cent. and the ordinary shareholders 20 per cent. We are placing another £5,000. to reserve, out of profits, and the fund will now amount to £120,000. Our profits are £12,000 more this year, after providing over £3,000 for the employees' benefit fund, pensions, war allowances, etc. On the credit side the cash at bankers is lower, but our trade debtors make up the difference, which has, of course, since come in. Investments are at the same figure as in last year's accounts, and they exceed the value quoted on the London Stock Exchange at the end of September, 1919. The nominal capital of the company has been increased by £150,000. in accordance with the resolution passed last October, but we only considered it necessary to issue £50,000., all of which was taken up by the ordinary shareholders. We have now been associated with Messrs. Lever Brothers for five years, and next month the majority of Pears' employees will enter the co-partnership scheme of that firm, and become part proprietors of that business without any contribution to its share capital.

Mr. John French seconded the motion, which was carried unanimously.

Mason and Barry, Ltd.

The directors regret to inform the shareholders that the position of the company shows no improvement from what it was at the time of the annual meeting last April. Although the price of copper is higher than at that date and the rate of exchange between Portugal and this country more in favour of the company, food and other conditions on the mine are worse and costs therefore continue to rise. Great difficulty in securing tonnage still continues, with the result that shipments of ore from the company's port of Pomaron up to September 30 only amounted to 23,790 tons, compared with 19,371 tons in 1918, 35,724 tons in 1917 and 151,424 tons in 1916, all up to same date.

Young's Paraffin Light and Mineral Oil Company, Ltd.

The directors announce that 27 per cent. of the B Debenture holders have not accepted the offer for the abandonment of their contingent rights, and the Anglo-Persian Oil Company have withdrawn their offer, but will reconsider the matter in the event of the minority seeing their way to agree within a reasonable time.

AMERICA AND GERMAN DYES.—*Reuter's* New York correspondent reports that American users of dyestuffs consider the domestic products unsuitable, and may apply to the War Trade Board for permission to import from Germany amounts sufficient to meet the requirements from November 15, 1919, to May 5, 1920.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

Canada.

A firm of manufacturers' agents in Winnipeg desire to represent United Kingdom manufacturers of glues on a commission basis. (Reference No. 855.)

The following inquiry has been received at the office of the High Commissioner for Canada, 19, Victoria Street, London, S.W. 1. All replies should be sent direct to the foregoing address: A Montreal company, a director of which is at present in this country, seek agencies of United Kingdom manufacturers of aniline dyes and chemicals.

Belgium.

A firm at Tournai desire to secure an agency for United Kingdom manufacturers of dyes, chemical products, and caustic potash for soap makers. (Reference No. 862.)

Czecho-Slovakia.

An agent of good standing wishes to act as agent to United Kingdom firms exporting drugs, chemicals, oils, and dye-stuffs. (Reference No. 868.)

Italy.

A firm of agents in Rome desire to get into communication with United Kingdom manufacturers of soap with a view to undertaking agencies in these lines. (Reference No. 871.)

Spain.

H.M. Commercial Secretary, Madrid, reports that a Spanish agent in Barcelona desires to get into touch with United Kingdom firms who are prepared to deal, on a commission basis, in aniline dyes, chemical products, perfumes, paints, and varnishes. (Reference No. 874.)

Switzerland.

An experienced Swiss business man desires to represent, in Switzerland, well-established United Kingdom exporters of chemicals and metals. (Reference No. 876.)

CORRESPONDENCE.

***We do not hold ourselves responsible for the opinions expressed by our correspondents.*

Dyestuffs Licensing System: the British Chemical Trade Association's Protest.

To the Editor of "*The Chemical Trade Journal and Chemical Engineer.*"

Sir,—I should be glad if you will permit me, through the columns of your valued paper, to request that any forms of petition in regard to the above, which are still outstanding, should be returned to this office forthwith.—Yours, etc.,

THE BRITISH CHEMICAL TRADE ASSOCIATION.

O. F. C. BROMFIELD, Assist. Sec.

80, Fenchurch Street, London, E.C. 3, October 20, 1919.

[If our correspondents "Merchant" and "Another Dealer" will forward their names and addresses, publication of their letters will be considered. We do not recognise anonymous communications.—Ed., *C.T.J. and C.E.*]

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London, 90%, 2s. to 2s. 1d.; North, 1s. 11d. to 2s.; 50%, 1s. 10d. to 1s. 11d.; North, 1s. 9d. to 1s. 10d.; naked; pure, 3s., naked, at works. Carbolic acid, crude, 60%. East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 3½d. to 9d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch, 77s. 6d. to 80s.; East Coast, 70s. to 75s., f.o.b.; West Coast, 62s. 6d. to 65s.; f.a.s. Solvent naphtha, naked, London, 90-190%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-160%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha, naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthaline, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 5¾d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid, 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b. other ports. Sulphate of ammonia: home trade, October £20. 10s., November £20. 15s., basis 24½%. Nitrate of soda, £22. to £22. 10s.

FERTILISER MATERIALS.

LIVERPOOL, THURSDAY.

Nitrate of soda is very firm, the quotation on spot for 95-96% quality being £20. 2s. 6d. per ton, net cash, f.o.r. Liverpool, prompt delivery. East Indian bone meal for shipment is without alteration, the quotation for November-December shipment being £17. 10s. per ton, net cash, ex ship Liverpool, for 4½% ammonia and 62% phosphate; on spot, Liverpool, holders ask £16. per ton, net cash, for 4½% and 45% quality. Mineral Phosphates: There is no change to report in this market, and values at present are only nominal. Dried blood supplies are scarce, the value being about 30s. per unit of ammonia per ton.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £104. 10s. to £104. 15s., cash; £104. to £104. 5s., three months; electrolytic, £116. to £121. Tin: Standard, £279. to £279. 5s., cash; £280. to £280. 5s., three months; Straits, £279. 5s.; English, £278. to £280. Lead: Soft foreign, £29. 15s.; English, £30. 10s.

Spelter, £45. 10s.; hard, £32. to £33.. Antimony, English regulus, 90%, £47. 10s. Aluminium £150. Nickel £205., delivered; packages extra. Quicksilver, £16. 15s. to £17. Bismuth, 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

TURPENTINE MARKET REPORT.

Messrs. James Watt and Son, Ltd., of 101, Leadenhall Street, London, E.C. 3, report that the stocks of turpentine on October 18 were: American, 36,177 barrels, compared with 4,472 barrels at the corresponding date of 1918; French, 818 barrels (748 barrels); and Spanish, 421 barrels (611 barrels). Deliveries during the week ended October 18 were 2,196 barrels, against 459 barrels last year, and since January 1, 59,192 barrels, compared with 20,228 barrels in 1918. The price on Saturday last was 125s. per cwt., compared with 105s. at the corresponding date of last year. October-December delivery was quoted at 125s., and January-April (1920) 126s. 6d.

SWANSEA MARKET REPORT.

THURSDAY.

Tinplates are held very firmly, the quotations being between 39s. and 40s. per standard box. Copper, £107. prompt, and £106. 5s. three months. Tin firm, with fair business at £281. cash and £282. 5s. three months. Lead firm and dearer at £29. for foreign and £30. for English. Spelter advanced to £45. per ton. Silver, 64½d. per ounce. Aluminium, £150. per ton. Nickel, £205. per ton, including delivery London or equal. Antimony nominal, with English regulus, 90%, at £45. Quicksilver, £16. 10s. per bottle. Sulphate of copper remains very quiet at £40. per ton. Sulphate of ammonia, very steady at £20. 10s. per ton basis. Nitrate of soda, quietly steady at 21s. 9d. per cwt., in bags, net. Castor oil, 98s. per cwt. in barrels. Rape oil in better request at 111s. per cwt. in barrels. Palm oil very firm and slightly dearer: Lagos, £84. 15s.; Benin, £83.; and hard, £81. Petroleum selling well at 1s. 6½d. to 1s. 7½d. per gallon in casks for American refined. Turpentine steady at £6. 6s. 6d. per cwt. Pitch rather scarce at 62s. 6d. per ton ex ship. Arsenic shows improvement, and prices are round £60. per ton for white powdered in bags f.o.b. Oxalic acid rather quiet at 1s. 2d. per lb. f.o.b. Copperas in fair request at £3. 10s. to £4. per ton delivered.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

Trade generally, both in home and export branches, continues very satisfactory, and values all round show an improving tendency. Resale lots of caustic soda, 70%, are firm at £24. 10s.; and there is an active demand for 58% alkali at £10. per ton, f.o.b. Refined bicarbonate of soda quiet at £8. 5s., in bags. Bleaching powder, softwoods, £17. on rails, casks returnable. Chlorate of soda in good request at 6d. per lb. Potash dull at 1s. per lb. Spot supplies of bichromate of soda are scarce, and price is higher at 10d. for resale lots. Roasted saltcake firm at 70s. per ton, carriage paid. Sulphate of copper in only small request, and export price nominal at £40., f.o.b. Recovered rock sulphur, £16. 10s. on rails. Phosphate of soda, steady at £28. per ton, in bags. Commercial hyposulphite of soda, unchanged at £16. 10s., in bags. Sulphite of soda, £11. per ton. Supply of white arsenic is still short, and price firm for best brand at £60. per ton. Yellow prussiate of potash quiet at 1s. 9d. per lb. Soda higher at 11½d. per lb., with strong inquiry. Carbonate of potash, £100. per ton; basis 85%. Lead salts are moving off steadily: White acetate at £83. and brown £68. per ton. Nitrate dull at £56. per ton. Acetic acid is well maintained at recent rates. Acetate of soda in better request, and price steady at £49. per ton. English brown acetate of lime firm at £12. per ton.; grey £17. per ton. Miscible wood naphtha, 10s. 6d. per gallon. Nitrate of soda unchanged at £60.; basis 100%. Green copperas is selling more freely. Oxalic acid steady at 1s. 1½d. per lb., delivered.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

The inquiry for chemicals has been well maintained, and a fairly active demand on export account is now being made. Bleaching powder has been in very fair request. It is £17. per ton for the home trade, free on rail or conveyance in buyers' packages, and £15. to £18. per ton for export. Chloride of calcium has been steadily called for, and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has had a brisk inquiry, especially on export account. It is £24. per ton for 76%, £22. per ton for 70 to 72%, and £19. per ton for 60

to 62%. Nitrate of soda has been more in demand, and is £21. to £22. per ton. Saltcake has been in rather active inquiry, and is £6. 10s. per ton, in casks, f.o.b. Soda crystals have been sold with some freedom, and are £5. 10s. per ton, in 2cwt. bags, f.o.r. at works. Bicarbonate of soda has been in good request, and is £8. 5s. to £10. per ton, according to terms of delivery. Borax continues to be freely inquired for, and spot stocks are still very light. Ordinary is £50. per ton, and powdered £51. to £52. per ton, in bags. Ammonia alkali has been in brisk demand, and is £6. 10s. to £6. 15s. per ton, f.o.r. at works. Hyposulphite has been quiet, and is £16. per ton for ordinary, and £21. per ton for pea crystals, in 1cwt. bags. Sulphite of sodium has been quieter, and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals, in 1cwt. kegs. Bichromate of soda has been more in request, and is 9d. per lb. Phosphate of soda has been in moderate demand, and is £25. per ton. Sulphide of sodium has been in fair request, and is £20. per ton in casks, and £22. per ton in drums. Chlorate of potash has been in somewhat freer inquiry, and the price is easier. It is 1s. per lb. Permanganate of potash has been quiet. The price is somewhat lower, and may be given as from 3s. to 3s. 3d. per lb. Sulphate of potash has been inactive, and is £30. per ton. Carbonate of potash has been in very fair demand, and is from £95. to £100. per ton for 80 to 85%. Caustic potash has been in good request, and is £120. per ton. Nitrate of potash has sold more freely, and is £55. to £60. per ton for refined, and £40. per ton for ordinary. Canadian potashes have been inactive. First quality Montreal are £200. to £220. per ton, and second quality £190. to £210. per ton. Bichromate of potash has sold a little more freely, and is 1s. 6d. to 1s. 7d. per lb. Yellow prussiate of potash has been in moderate demand, and is 1s. 9d. to 1s. 10d. per lb. Salammoniac has been more in request, and is £95. per ton for first quality lump, £85. per ton for second quality, and £5. per ton extra for crushed. Sulphate of ammonia has been but little in request, and is £20. 10s. per ton for October, £20. 15s. for November, £21. for December, £21. 7s. 6d. for January, 1920, £21. 15s. for February, and £22. per ton for March to May, 1920. Carbonate of ammonia has been in quietly steady demand, and is 6½d. per lb. Muriate has had a limited sale, and is £48. to £50. per ton. Magnesia has been in very fair request. Carbonate is £2. 5s. per cwt., and sulphate £11. to £16. per ton, according to grade. Alum continues to meet with a good inquiry, and stocks available for early delivery are still very small. Prices are: For home-trade uses, £18. 10s. per ton; for export, £18. 10s. to £19. 10s. per ton. Aluminoferric has been but little called for, and is £8. 10s. to £12. per ton, according to quality. Sulphate of alumina has again been quiet, and is £12. to £17. per ton, according to grade. Sulphur has been well inquired for. English flowers are £32. per ton, roll is £28. per ton, and rock £22. per ton, in bags, f.o.r. Sicilian grades are: Flowers, £28. per ton; roll, £22. 10s. per ton; and rock, £17. 15s. per ton. Cream of tartar has been steadily called for, and has been scarce. The price has hardened, and may be given as £12. to £12. 10s. per cwt. Tartaric acid has been in very fair request, and is 3s. 1d. to 3s. 2d. per lb. Boracic acid has been quieter. Crystals are £80. per ton, and powdered £82. per ton, in bags, and from £2. to £3. per ton extra in casks. Oxalic acid has been rather more inquired for, and is slightly easier in price. It is 1s. 1d. to 1s. 2d. per lb. Citric acid has sold rather more freely, and is 4s. 3d. to 4s. 4d. per lb. White acetate of lead has been in moderate demand, and is £85. per ton. Arsenic has been in quietly steady request, and the price has eased. White powdered is £58. to £60. per ton. Sulphate of copper has been but little called for, and prices are somewhat lower; from £40. to £41. per ton for home trade lots, and from £41. to £42. per ton for export, less 5% in casks, f.o.b. at Liverpool, are being quoted.

TYNE CHEMICAL REPORT.

TUESDAY.

Market is firm, and there is a brisk demand for chemicals, especially for the house market. There is also an improved inquiry for export, and more business passing. Locally, soda crystals are in strong request at £5. 10s. per ton in 2cwt. bags. Sulphur scarce at £22. to £23. per ton.

The following prices are per ton, net: Bleaching powder, softs, £17.; caustic soda, 76 7/7%, £24.; do., 70%, £22.; do., 60%, £20.; recovered sulphur, 2cwt. bags, £22.; hyposulphite of soda, 5/7cwt. casks, £19.; 1cwt. kegs, £25.; sulphite of soda, 5/7cwt. casks, £12., do., 1cwt. kegs, £20.; silicate of soda, 75Tw., £9. 12s. 6d., do. 100Tw., £10., do., 140Tw. £10. 10s.; soda crystals, 2cwt. bags, £5. 10s.; sulphate of soda (salt

cake) in bulk, £4.; pure white sulphate of alumina, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18.; do., refined concentrated solid, 60/62%, £25.; hydrate of barium, crystals, £56.

COALS.—Market is very firm, with a strong demand for prompt loading. The supply of tonnage is rather better, and any surplus coal is being readily taken up. Quotations nominally: Best Northumbrian steam, 95s. to 100s. per ton, seconds, 90s. to 95s.; Northumberland small coals, 75s. to 80s., seconds, 70s. to 75s.; best Durham gas coals, 80s. to 85s., seconds, 65s. to 75s.; Durham Bunkers, 70s. to 80s., seconds, 60s. to 65s.; foundry coke, 100s.; gas coke, 95s. to 100s.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Wednesday.

During the past week there was a continued good demand for most classes of heavy chemicals, and prices on the whole were maintained at a steady level—with however, a slight tendency in some cases to lower values. Saltpetre, for instance, is now quoted at £3. as against £3. 2s. previously; but on the other hand tartaric acid has jumped from 3s. 3d. to 3s. 6d. per pound, and caustic soda from £24. to £25. per ton. Current quotations are:—Arsenic, £62. per ton, net, Glasgow; bicarbonate of soda, £9. 15s. and £10. 10s. per ton for 6-8 casks and 1cwt. kegs, net, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags; and borax

crystals, £39. for 2cwt. bags, carriage paid; caustic soda, white, 70-72%, £25. per ton, net, Glasgow; chlorate of potash, 1s. 1d. per lb., net, Glasgow; chlorate of soda, 8d. per lb., net, Glasgow; citric acid, 4s. 4d. per lb., 5%, Glasgow; cream of tartar, 98%, £11 10s. per cwt., net, Glasgow; paraffin wax, U.K. deliveries, 125°, 6½d. to 6¾d.; 121-3°, 5½d. to 5¾d.; 118-20°, 5d.; 110-12°, 4d. to 4½d.; and 98-102°, 4d. to 4½d.; salammuniac, £80. and £75. per ton, net, any port, for first and second lump respectively; salammuniac crystals, £85. per ton, net, Glasgow; saltpetre, £3., net, Glasgow; tartaric acid, 3s. 6d. per lb., 5%, Glasgow.

Among the sea oils, prices do not show very much fluctuation over previously quoted values, but where any change is noted this is in a lowering direction. Among whale oils, for instance, the pale variety is now on offer at 90s. as against 95s. previously, but both brown and black remain stationary at the old figures of 76s. and 74s. respectively. Again, Menhaden is also lower in value at 80s. as against 82s. previously, but there are no changes with regard to Newfoundland cod, at 80s., and pale seal at 96s. Demand is good and usually more than equal to the supply.

Matters in the local coal trade continue to be pretty much on the old footing. From the industrial standpoint the demand for fuel is well maintained, while requirements for household purposes are getting heavier as the colder season sets in. The output generally is being maintained at a good level and stocks are not allowed to accumulate long at the pithead.

Amsterdam, 2 cs., £18.; Melbourne, 1 cs., £32.

BENZOIC ACID

Canton, 17 cs. (pt.), £8.; Christiania, 1 brl., £30.

BISMUTH

Melbourne, 1 cs. (pt.), £15.; Toronto, 2 cs., £160.

BISMUTH CARBONATE

Durban, 1 cs. (pt.), £22.; Melbourne, 2 cs., £92.; Shanghai, 1 cs., £25.; Sydney, 3 cs., £221.

BISMUTH SALICYLATE

Mauritius, 1 cs. (pt.), £20.; Sydney, 1 cs. (pt.), £10.

BISMUTH SALTS

Marseilles, 1 cs. (pt.), £25.

BISMUTH SUBGALLATE

Sydney, 1 cs. (pt.), £11.

BISMUTH SUBNITRATE

Buenos Ayres, 1 cs., £76.; Bombay, 1 cs. (pt.), £41.; Constantinople, 2 cs. (pt.), £74.; Dantzig, 1 cs., £147.; Lisbon, 1 cs. (pt.), £100.; Mauritius, 1 cs. (pt.), £10.; Melbourne, 1 cs., £19.; Pt. Swettenham, 1 cs. (pt.), £7.; Shanghai, 1 cs., £104.; Sydney, 1 cs. (pt.), £48.; Talcahuano, 1 cs. (pt.), £10.; Valparaiso, 1 cs. (pt.), £20.

BORAX

Antwerp, 15 t. 3 c., £763.; Bermuda, 5 c., £23.; Buenos Ayres, 20 t. 9 c., £797.; Calcutta, 6 t., £234.; Durban, 3 c., £7.; Christiania, 1 t., £40.; Constantinople, 1 t., £57.; Paris, 5 t. 10 c., £225.; Rotterdam, 12 t., £600.; Sydney, 5 c., £11.

BORIC ACID

Alexandria, 1 t. 5 c., £92.; Belgrade, 1 t., £70.; Buenos Ayres, 5 t. 1 c., £547.; Constantinople, 1 t., £98.; Iquique, 4 c., £29.; Jamaica, 2 c., £9.; Limon, (F.), 2 c., £9.; Montreal, 4 c., £16.; Piraeus, 5 c., £19.; Pekin, 3 c., £12.; Punta Arenas, 1 c., £7.; Rotterdam, 3 t. 19 c., £289.; Shanghai, 10 c., £39.

CALCIUM CARBIDE

Amsterdam, 14 t. 15 c., £360.; Cyprus, 10 c., £27.; Malta, 10 cs., £12.; Punta Arenas (F.), 1 t. 10 c., £36.

CALCIUM CHLORIDE

Auckland, 4 c., £30.; Caen, 5 c., £14.; Colombo, 10 c., £7.; Havre, 1 t. 11 c., £77.; Paris, 1 t. 10 c., £94.

CALCIUM HYPOPHOSPHITE

Paris, 4 cs., £102.

CARBIDE

Kilindini, 2 c., £8.; Mossel Bay, 4 c., £18.; Pt. Elizabeth, 2 t., £18.; Suez, 6 c., £8.

CARBON BISULPHIDE

Copenhagen, 50 drms., £100.; Durban, 4 cs., £19.

CARNAUBA WAX

Christiania, 10 c.; Genoa, 1 t.; Leghorn, 1 t.

CAUSTIC POTASH

Canton, 16 pkgs. (pt.), £9.; Melbourne, 1 cs. (pt.), £7.; Valparaiso, 1 ck., £98.

CAUSTIC SODA

Gibraltar, 6 c., £11.; Larache, 10 c., £20.; Port Said, 10 c., £21.; Rotterdam, 1 t., £9.

CERESINE WAX

Antwerp, 16 c.; Yokohama, 3 t. 10 c.

CHEMICALS (otherwise undescribed)

Antwerp, 4 cs., £168.; Auckland, 1 cs., £10.; Antigua, 1 cs., £7.; Bombay, 11 cs. (pt.), £86.; Brisbane, 3 cs., £55.; Cape Town, 4 cs., £67.; Copenhagen, 7 pkgs., £101.; Christiania, 5 cs., £46.;

CHEMICALS (otherwise undescribed)

Grenada, 4 cs., £139.; Durban, 9 cs., £167.; Christchurch, 1 cs., £14.; East London, 3 cs., £31.; Lyttleton, 1 ck., £13.; Melbourne, 3 cs., £45.; New York, 3 cs., £320.; Pt. Swettenham, 2 cs. (pt.), £23.; Penang, 8 pkgs. (pt.), £19.; Shanghai, 4 pkgs., £99.; Singapore, 3 cs., £70.; Sydney, 5 pkgs., £94.; Wei-hai-Wei, 1 cs., £10.; Wellington, 7 cs., £66.

CHLORIDE OF LIME

Delagoa Bay, 10 c., £20.

CHLOROSULPHURIC ACID

Switzerland, 23 drms., £440.

CHRYSAROBIN

New York, 1 cs., £130.

CHRYSOPIANIC ACID

Canton, 17 cs. (pt.), £24.

CITRIC ACID

Barcelona, 1 t. 19 c., £937.; Belawan, 4 cs., £10.; Bombay, 4 c., £104.; Calcutta (F.), 3 c., £68.; Christiania (F.), 2 c., £34.; East London, 1 cs. (pt.), £5.; Fremantle, 1 c., £26.; Kobe, 2 t. 10 c., £115.; New York, (F.), 5 t. 5 c., £2467.; Piraeus (F.), 5 c., £126.; Pt. Elizabeth, 5 c., £129.; St. Vincent, W.I. Is., 1 c., £26.; Talcahuano, 1 cs. (pt.), £6.; Trinidad (F.), 1 c., £18.

COBALT RESINATE

Brussels, 2 cks., £48.

COPPERAS

Sydney, 1 cs., £8.

COPPER ACETATE

Sydney, 1 cs., £14.

COPPER CHLORIDE

Amsterdam, 10 cks., £209.

COPPER SULPHATE

Durban, 3 c., £8.; Rio de Janeiro, 1 t., £47.; Rotterdam, 1 t., £40.

COPPER SULPHOCYANIDE

Malmo, 10 drms., £52.

CREAM OF TARTAR

Adelaide (F.), 1 t. 6 c., £299.; Bangkok (F.), 2 cs., £8.; Bombay (F.), 2 c., £34.; Brisbane (F.), 3 t., £690.; Calcutta (F.), 4 c., £70.; Constantinople, 2 c., £35.; Durban (F.), 3 c., £30.; East London, 2 c., £36.; Hong Kong, (F.), 4 c., £65.; Iquique, 1 c., £19.; Kilindini (F.), 1 c., £12.; Karachi (F.), 2 c., £32.; Singapore (F.), 1 c., £12.; Talcahuano, 2 c., £39.; Trinidad (F.), 2 c., £27.

DIETHYLBARBITURIC ACID

Lisbon, 2 cs. (pt.), £5.

DISINFECTANTS

Aden, 2 c., £6.; Antigua, 2 c., £8.; Bangkok, 2 t. 5 c., £90.; Beyrout, 1 c., £11.; Bombay, 1 t. 15 c., £86.; Canton, 4 t., £132.; Cape Town 3 t. 12 c., £126.; Calcutta, 1 t. 16 c., £94.; Colombo, 6 t. 3 c., £179.; Durban, 12 c., £98.; East London, 4 c., £12.; Foochow, 4 c., £6.; Jamaica, 1 t. 10 c., £59.; Lobiti Bay, 2 c., £10.; Malta, 10 c., £49.; Melbourne, 4 c., £11.; Montreal, 3 t. 12 c., £206.; Piraeus, 8 c., £42.; Pt. Elizabeth, 11 c., £45.; Penang, 6 c., £19.; Port Sudan, 2 t. 15 c., £105.; Perth, 4 c., £11.; Rangoon, 9 t. 7 c., £156.; St. Johns N.F., 3 t. 13 c., £252.; Shanghai, 3 t. 14 c., £130.; Sydney, 4 t. 19 c., £229.; Swatow, 4 c., £12.; Tientsin, 1 t., £36.; Trinidad, 17 c., £30.

ETHER

Cyprus, 1 cs., £7.; Piraeus, 10 cs., 51 cs. (pt.), £660.; Samarang, 2 cs. (pt.), £28.

ETHER (ACETIC)

Calcutta, 2 cs., £32.; Canton, 1 cs., £12.; Pekin, 1 cs., £8.

ETHER (METHYLIC)

Bombay, 1 cs. (pt.), £4.

ETHER (SULPHURIC)

Bombay, 3 cs. (pt.), £26.; Lisbon, 7 cs., £55.; Rangoon, 1 cs., £5.

ETHYL CHLORIDE

Bombay, 1 cs. (pt.), £12.

FATTY ACIDS

Dunkirk, £2,280.

FLUORIC ACID

Madras, 1 cs. (pt.), £6.

FORMALDEHYDE

Alexandria, 1 ck., £24.; Christiania (F.), 9 cks., £200.; Iquique, 2 cs., £11.; Melbourne (F.), 3 cs., £66.; Piraeus (F.), 2 cs. (pt.), £7.

FULLER'S EARTH

Montreal, 2 c.; New York, 1 t.

GALLIC ACID

Bombay, 1 cs. (pt.), £20.; Kobe (F.), 4 brls., £168.; Rotterdam, 1 brl., £60.

GELATINE

Chemulpo, 3 c.

GLUE

Wellington, 10 e.

GLUE PITCH

Boston, 1 t. 17 c.

GLUE, SIZE, AND GELATINE

Amsterdam, 2 t.; Antwerp, 1 c.; Bangkok, 10 c.; Barcelona, 8 c.; Bilbao, 3 t.; Bombay, 2 c.; Christchurch, 1 c.; Cape Town, 1 t. 16 c.; Copenhagen, 1 t. 17 c.; Dunedin, 2 t.; Durban, £34.; East London, 2 c.; Fremantle, 8 c.; Gothenburg, 1 t.; Helsingfors, 5 t.; Hong Kong, 2 t. 5 c.; Karachi, 2 c.; Madras, 1 c.; Pt. Elizabeth, 1 c.; Rangoon, 12 c.; Rotterdam, 1 t. 15 c.; Singapore, 1 t. 2 c.; Sydney, 2 t. 4 c.

GLYCERINE

Alexandria, 1 c., £7.; Bombay, 4 c., £41.; Bordeaux, 5 t., £658.; Calcutta, 2 c., £20.; Canton, 2 c., £14.; Constantinople, 1 c., £11.; Galatz, 5 t., £625.; Havre, 1 t., £120.; Mossel Bay, — c., £6.; Pekin, 3 c., £22.; Paris, 4 t. 17 c., £680.; Piraeus, 2 c., £22.; Pt. Elizabeth, 1 c., £8.; Rotterdam, 10 c., £60.; Rouen, 8 t. 1 c., £770.; Salonica, 6 c., £40.; Samarang, 1 c., £7.; Shanghai, 10 c., £56.; Valparaiso, 2 c., £19.; Zanzibar, 1 c., £6.

GLYCEROPHOSPHATE OF LIME

Lisbon, 1 cs. (pt.), £9.

GUANO

New York, 1 t., £22.

HYDROCHLORIC ACID

Alexandria, 1 t., £50.; Belawan, 3 c., £10.; Bombay, 2 c., £6.; Cape Town, 1 c., £7.; Colombo, 12 c., £59.; Trinidad, 2 t., £80.

HYDROFLUORIC ACID

Pt. Elizabeth, 4 c., £56.

HYDROGEN PEROXIDE

Alexandria, 2 crbys., 8 cs., £25.; Cyprus, 3 cs., £8.; Madras, 11 cs. (pt.), £12.; Mossel Bay, 1 cs., £7.; Pt. Elizabeth, 2 cs., £8.

HYDROQUINONE

Bombay, 1 cs. (pt.), £17.

IODINE

Alexandria, 1 cs., £101.; Genoa (F.), 10 cks., £5,916.

IODINE (RESUBLIMED)

Buenos Ayres, 1 cs. (pt.), £45.; Shanghai, 1 cs. 2 cs. (pt.), £85.

IRON & AMMONIUM CITRATE

Bilbao, 2 cs., £57.; Montreal, 3 cs., £125.; Moss, 3 cs., £124.; Rotterdam, 2 cs., £60.

IRON SULPHIDE

Durban, 1 ck., £6.

LACTIC ACID

Brussels, 7 cks., £130.; Melbourne, 1 cs., 5 cks., £97.; Piraeus, 20 cks., £520.; Talcahuano, 1 cs. (pt.), £6.

LEAD ACETATE

Bombay, 60 kgs., £207.; Lisbon, 4 kgs., £18.; Gothenburg, 18 kgs., £428.

LEAD ARSENATE

Auckland, 24 drms., 2 cks., £30.; Delagoa Bay, 2 cks., £15.

MAGNESIA (CALCINED)

Alexandria, 1 cs. (pt.), 5 cs., £42.; Bombay, 3 cs., £18.; Constantinople, 3 cks., £9.; Lisbon, 4 cks., 1 cs., £82.; Marseilles, 1 cs. (pt.), £7.; Rouen, 40 cs., £176.

MAGNESIUM CARBONATE

Boulogne, 40 bgs., £108.; Bombay, 6 cs., £30.; Foochow, 1 cs., £5.; Melbourne, 40 cks., £130.; Piraeus, 1 ck., £5.; Shanghai, 150 bgs., £375.; Sydney, 2 cs., £11.

MAGNESIUM CITRATE

Bermuda, 1 cs., £5.; Limon, 3 cs., £36.; Pt. Elizabeth, 1 cs., £6.

MAGNESIUM SULPHATE

Alexandria, 7 c., £13.; Bermuda, 3 c., £7.; Cyprus, 6 c., £15.; East London, 9 c., £14.; Guayaquil, 8 c., £20.; Karachi, 2 c., £7.; Kilindini, 4 c., £7.; Malacca, 10 c., £11.; Mauritius, 6 c., £10.; Seville, 16 c., £44.; Shanghai, 1 t., £34.

MANGANESE ACETATE

Boulogne, 1 ck., £90.

MANGANESE BORATE

Genoa, 10 c., £36.; Rouen, 3 c., £8.; Stockholm, 3 cks., £60.

MANGANESE HYDRATE

Genoa, 1 ck., £15.

MANGANESE RESINATE

Stockholm, 6 cks., £72.

MERCURY BICHLORIDE

Bombay, 1 cs., £25.; Rangoon, 4 cs., £157.

MERCURY OXIDE

Beyrout, 1 cs. (pt.), £11.; Switzerland, 1 cs. (pt.), £7.

MERCURY PERCHLORIDE

Beyrout, 1 cs. (pt.), £33.; Toronto, 1 cs., £40.

METHYL ALCOHOL

Bombay, 1 cs. (pt.), 2 cs., £21.; Buenos Ayres, 1 cs., £7.

METHYL SALICYLATE

Belgrade (F.), 1 cs., £9.; Lisbon, (F.), 1 cs., £11.

MURIATIC ACID

Buenos Ayres, 3 cs., £9.; Rosario, 4 cs., £12.

NICKEL SALTS

Pt. Chalmers, 1 ck., £6.

NICKEL SULPHATE

Paris, 3 cks., £17.; Rotterdam, 45 cks., £560.; Yokohama, 50 cs., £150.

OXALIC ACID

Calcutta, 2 cks., £21.; Cape Town, 1 kg., £8.; Paris, 21 cks., £706.; Piraeus, 3 cks., £51.

PHOSPHORIC ACID

Durban, 1 cs., £7.; Montreal, 21 cs., £105.; Paris, 149 crbys., £1,447.; Yokohama, 2 cs., £91.

PLUMBAGO

Malaga, 1 t.

POTASSIUM ACETATE

Bombay, 1 cs. (pt.), £5.; Cape Town, 1 cs., £5.

POTASSIUM BICARBONATE

Italy (F.), 1 c., £19.

POTASSIUM BROMIDE

Bombay, 1 cs. (pt.), 2 cs., £45.; Canton, 17 cs. (pt.), £9.; Piraeus, (F.), 1 cs. (pt.), £5.; Shanghai, (F.), 1 cs. (pt.), £8.; Valparaiso, 1 cs. (pt.), £3.

POTASSIUM CARBONATE

Alexandria, 1 cs., £18.; Genoa (F.), 5 t., £860.; Talcahuano, 1 cs. (pt.), £6.

POTASSIUM CHLORATE

Calcutta, 1 c., £10.; Iquique, 2 c., £24.

POTASSIUM CITRATE

Bombay, 3 cs., £180.; Canton, 17 cs. (pt.), £15.; Pt. Swettenham, 1 cs. (pt.), £8.; Shanghai, 1 cs., £14.; Sydney, 2 cs., £57.; Toronto, 1 cs. (pt.), £14.

POTASSIUM CYANIDE

Bombay, 1 cs., 1 cs. (pt.), £227.; Buenos Ayres, 14 cs., £186.;

POTASSIUM CYANIDE—

Christchurch, 1 cs., £10.; Singapore, 9 cs., £182.

POTASSIUM FERROCYANIDE—

Bilbao, 1 kg., £33.

POTASSIUM IODIDE—

Alexandria, 1 cs., £85.; Buenos Ayres, 1 cs. (pt.), £40.; Durban, 1 cs. (pt.), £10.; Melbourne, 1 cs., £46.; Pt. Swettenham, 1 cs. (pt.), £39.; Shanghai, 2 cs. (pt.), £55.

POTASSIUM METABISULPHITE—

Algiers, 10 cks., £210.; Italy, 4 cks., £43.; Paris, 4 cks., £205.

POTASSIUM PERMANGANATE—

Bombay, 1 t., £364.; Constantinople, 1 cs. (pt.), £40.; Lisbon, 1 cs. (pt.), £15.; Perth, 1 cs., £20.; Valparaiso, 2 cs. (pt.), £56.

POTASSIUM PRUSSATE—

Durban, 1 brl., £15.; Pt. Swettenham, 2 c., £28.

POTASSIUM SILICATE—

Bilbao, 1 t. 10 c., £104.

POTASSIUM SULPHATE—

Alexandria, 2 cs., £22.; Valparaiso, 1 cs. (pt.), £8.

PYRAMIDON—

Kobe (F.), 2 cs., £577.

PYRO ACID—

Amoy, 1 cs., £8.; Batavia, 1 cs. (pt.), £9.; Bangkok, 1 cs. (pt.), £6.; Shanghai (F.), 2 cs. (pt.), £14.

QUININE—

Bombay, 1,000 ozs.; Calcutta, 1,089 ozs.

RESORCIN—

Valparaiso, 1 cs. (pt.), £27.

ROSIN—

Batoum, 8 c.

SALACETOS—

Paris, 5 brls., £103.; Sydney, 5 cs., £46.

SALAMMONIAC—

Bombay, 4 t. 13 c., £327.; Delagoa Bay, 1 c., £5.; Galatz, 1 t., £72.; Kilindini, 2 c., £8.; Toronto, 5 c., £19.

SALICYLIC ACID—

Canton, 17 cs. (pt.), £9.; Hong Kong, 2 cs., £6.; Shanghai, 2 cs., £11.

SALT—

Alexandria, 6 c.; Bombay, 2 t., 14 c.; Colombo, 13 c.; Karachi, 11 c.; Madras, 1 t.; Trinidad, 13 t.

SALTPETRE—

Alexandria, 2 t., £110.; Amsterdam, 2 t., £104.; Barcelona, 7 t., 9 c., £395.; Christiania, 2 t., £130.; Durban, 1 t. 3 c., £81.; Iquique, 2 c., £11.; Malta, 2 c., £7.; New York (F.), 118 t., 5 c., £3,550.; Oporto, 5 t. 11 c., £301.; Pacasmayo, 4 c., £13.; Valencia, 2 t. 11 c., £101.

SHEEP DIP—

Beira, 1 c., £8.; Buenos Ayres, 72 t. 6 c., £3,717.; Dunedin, 6 t. 5 c., £219.

SILVER NITRATE—

Piraeus (F.), 3 cs. (pt.), £14.; Rio de Janeiro, 1 cs. (pt.), £6.

SILVER NUCLEINATE—

Calcutta, 1 cs., £96.

SILVER PROTEINATE—

Belgrade (F.), 2 cs., £43.; Calcutta, 1 cs., £50.; Constantinople, 50 cs., £108.; Shanghai, 1 cs. (pt.), £8.

SILVER SALTS—

Pt. Chalmers, 1 cs. (pt.), £23.

SOAP—

Abo, 2 c.; Adelaide, 3 c.; Alexandria, 3 t. 5 c.; Aden, 9 c.; Amsterdam, 6 c.; Antwerp, 232 t. 15 c.; Auckland, 1 c.; Bangkok, 5 c.; Barcelona, 8 c.; Beira, 1 t. 1 c.; Bergen, 11 t. 7 c.; Beyrout, 2 t. 13 c.; Bilbao, 1 c.; Bombay, 3 t. 19 c.; Brisbane, 3 c.; Calais, 7 c.; Cape Town, 1 t. 1 c.;

SOAP—

Channel Islands, 4 c.; Christiania, 11 t. 11 c.; Cologne, 94 t. 15 c.; Colombo, 1 t. 7 c.; Constantinople, 11 c.; Copenhagen, 2 t. 5 c.; Drammen, 1 c.; Dunedin, 2 c.; Durban, 2 c.; Esbjerg, 5 c.; Galatz, 38 t. 11 c.; Gijon, 5 c.; Helsingfors, 50 t. 2 c.; Hobart, 1 c.; Hong Kong, 1 c.; Karachi, 2 c.; Kilindini, 5 c.; Lobito Bay, 10 c.; Lisbon, 2 c.; Malta, 3 c.; Marselles, 4 c.; Mauritius, 2 c.; Mombasa, 1 c.; Montreal, 16 c.; Morocco, 2 t. 10 c.; New Chang, 2 c.; New York, 2 t. 12 c.; Penang, 12 c.; Perth, 4 c.; Rangoon, 8 c.; Rotterdam, 26 t. 1 c.; Salonic, 1 t. 16 c.; St. Helena, 1 c.; St. John's, N.F., 2 t. 4 c.; St. John, N.B., 1 t. 17 c.; Seville, 2 c.; Shanghai, 8 c.; Singapore, 8 c.; Smyrna, 1 t. 19 c.; Tripoli, 1 t. 11 c.; Wellington, 3 c.; Yokohama, 10 c.

SODA—

Singapore, 4 t. 18 c., £38.

SODA ASH—

Cologne, 61 t. 15 c., £477.; Gothenburg, 26 t., £202.

SODA CRYSTALS—

Gibraltar, 1 t., £9.; Nassau, 7 c., £7.

SODIUM ACETATE—

Bombay, 1 kg., £7.

SODIUM AND TITANIUM**OXALATE**—

Christchurch, 1 ck., £25.

SODIUM ARSENITE—

Durban, 1 t. 18 c., £112.

SODIUM BENZOATE—

Alexandria, 1 cs. (pt.), £26.; Beyrout, 1 cs. (pt.), £6.; Buenos Ayres (F.), 1 cs. (pt.), £17.; Calcutta, 4 cs., £59.; Constantinople, 2 kgs., £55.; Mauritius, 1 cs. (pt.), £7.; Piraeus (F.), 5 cs. (pt.), £6.; Valparaiso, 1 cs. (pt.), £8.

SODIUM BICARBONATE

Bermuda, 1 t., £12.; Calcutta, 4 c., £14.; Canton, 5 c., £6.; Cologne, 27 t., £220.; Durban, 10 c., £16.; Iquique, 6 c., £6.; Pt. Elizabeth, 16 c., £26.; Rotterdam, 1 t., £13.; Shanghai, 10 c., £10.; Sydney, 4 c., £9.; Toronto, 4 c., £9.; Wellington, 5 c., £7.

SODIUM BICHRIMATE

Christiania (F.), 4 t., £317.

SODIUM BISULPHITE—

Antwerp, 10 t. 1 c., £286.; Pt. Swettenham, 2 t. 10 c., £79.; Singapore, 1 t., £24.

SODIUM BROMIDE—

Bombay, 1 cs., £14.; Constantinople, 1 cs. (pt.), £6.; Melbourne, 2 c., £36.; Sydney, 1 cs. (pt.), £7.

SODIUM CADODIATE—

New York (F.), 2 cs., £350.

SODIUM CARBONATE—

Batavia, 1 c., £5.; Buenos Ayres, 2 c., £5.; Salonic, 2 cs., £14.; Shanghai, 3 c., £13.; Singapore, 7 c., £14.

SODIUM CHLORIDE—

Alexandria, 3 t., £5.

SODIUM CYANIDE—

East London, 2 cs., £22.; Shanghai, 1 ck., 2 cs., £16.

SODIUM HYPO—

Amsterdam, 2 cks., £45.; Batavia, 10 c., £11.; Constantinople, 2 t. 15 c., £77.; Jaffa, 1 t., £27.

SODIUM HYPHOSPHITE—

Paris, 2 cs., £45.

SODIUM METHYLARSENATE—

Lisbon, 1 cs. (pt.), £6.

SODIUM PERBORATE—

Christiania (F.), 2 c., £31.

SODIUM PHOSPHATE—

Calcutta, 1 ck., £6.

SODIUM PRUSSATE—

Kobe, 34 t. 5 c., £2,626.; New York, 34 t. 19 c., £2,797.

SODIUM SALICYLATE—

Bombay, 2 cs., 1 cs. (pt.), £38.; Buenos Ayres (F.), 1 cs. (pt.), £7.; Constantinople, 1 cs. (pt.), £60.; Durban, 1 cs. (pt.), £8.; Melbourne, 2 cks., £66.; Piraeus, 1 ck., £10.; Sydney, 1 cs., 2 cks., £69.

SODIUM SILICATE—

Christiania, 9 t. 17 c., £138.; East London, 5 c., £9.; Larache, 13 c., £10.; Shanghai, 7 t. 3 c., £78.

SODIUM SULPHATE—

Penang, 18 c., £16.

SODIUM SULPHATE (GLAUBER SALTS)—

Alexandria, 1 t., £10.

SODIUM SULPHITE—

Batavia, 2 cks., £11.; Calais, 11 c., £305.; Copenhagen, 3 c., £8.; Christiania, 2 t., £44.; Pt. Swettenham, 1 t. 5 c., £30.; Salonic, 2 cs., £14.; Singapore, 7 c., £14.; Sydney, 5 c., £6.; Shanghai, 4 c., £18.

SODIUM TARTRATE—

Marseilles, 1 c., £6.

STEARINE—

Bordeaux, 10 t.

STRONTIUM NITRATE—

Bombay, 16 cks., £158.

SULPHATE OF LEAD—

Bombay, 8 cks., £152.

SULPHUR—

Alleppey, 3 c., £9.; Alexandria, 2 c., £5.; Cologne, 10 c., £15.; Cape Town, 18 c., £23.; Delagoa, 1 c., £9.; Punta Arenas (F.), 2 c., £6.; Rio Galleo, 15 t., £435.; Rotterdam, 1 c., £14.; Sydney, 2 c., £8.

SULPHUR (FLOWERS)—

Beira (F.), 4 c., £9.; Cape Town, 4 t. 9 c., £119.; Durban, 2 c., £6.; Lisbon, 3 c., £5.

SULPHURIC ACID—

Alexandria, 2 t., £92.; Brussels, 1 t. 4 c., £46.; Buenos Ayres, 15 c., £21.; Channel Islands, 1 t. 6 c., £15.; Demerara, 7 t. 10 c., £112.; Trinidad, 5 t., £80.

TALLOW—

Genoa, 14 t. 11 c.

TANNIC ACID

Buenos Ayres, 2 cs., £110.; Durban (F.), 1 cs. (pt.), £12.; Hobart (F.), 1 cs. (pt.), £6.; Iquique, 1 cs. (pt.), £31.; Vera Cruz, 1 cs. (pt.), £13.

TARTARIC ACID—

Bombay, 2 c., £38.; Calcutta (F.), 4 c., £85.; Canterbury, 1 c., £30.; Chinde, 1 cs. (pt.), £6.; Cape Town, 5 c., £91.; Cape Town (F.), 1 c., £18.; Christiania, 15 c., £296.; Christiania (F.), 11 c., £200.; Constantinople, 1 c., £28.; Colombo (F.), 1 c., £12.; Durban (F.), 3 c., £56.; Durban, 2 c., £43.; Fremantle, 3 c., £56.; East London, 2 c., £40.; Iquique, 1 c., £24.; Karachi, 1 cs. (pt.), £6.; Karachi (F.), 5 c., £112.; Kobe, 10 c., £187.; Madras (F.), 1 c., £22.; New York (F.), 1 t., £318.; Pt. Elizabeth, 5 c., £94.; Pt. Elizabeth (F.), 1 c., £18.; Pt. Sudan, 5 c., £82.; Singapore, (F.), 10 c., £159.; Talcahuano, 1 c., £28.

THEOBROMINE AND SODIUM**SALICYLATE**—

Belgrade, 1 cs., £22.

WHITE LEAD—

Alexandria, £282.; Antwerp, £274.; Auckland, £5.; Buenos Ayres, £593.; Calais, £1,235.; Christiania, £100.; Christchurch, £60.; Dantzig, £46.; Dunedin, £14.; Kilindini, £113.; Lisbon, £337.; Malta, £15.; Oamaru, £30.; Oporto, £73.; Paris, £185.; Piraeus, £381.; Singapore, £171.; Treport, £525.

ZINC SULPHATE—

Bombay, 34 cks., £48.

MANCHESTER.

Week ending October 14.

ALUM—

Antwerp, 150 pkgs.

CAUSTIC SODA—

Genoa, 102 drms.

COAL PRODUCTS (otherwise undes.)

Genoa, £13.; Piraeus, £145.; Volo, £129.

DYESTUFFS—

Logwood Extract

Genoa, 36 cs.

PITCH—

Antwerp, 689 t.

SOAP—

Antwerp, 650 cs., 67 pkgs.

SODA ASH—

Genoa, 500 bgs.

SODA CRYSTALS—

Piraeus, 50 bgs.

SODIUM BICARBONATE—

Antwerp, 482 bgs.

SODIUM BICHRIMATE—

Antwerp, 2 cks.

MIDDLESBROUGH.

Week ending October 18.

OLEINE—

Rotterdam, 12 t., £1,200.

SALT—

Antwerp, 310 t., £963.; Helsingborg, 222 t., £778.; Karlsruhe, 100 t., £350.

NEWCASTLE-ON-TYNE

Week ending October 18.

ANTIMONY—

Gothenburg, 4 t.; Rotterdam, 5 t.

BARIUM NITRATE

Genoa, 14 c.

BLEACHING POWDER—

Gothenburg, 43 t.; Rouen, 70 t.

CAUSTIC SODA

Gothenburg, 55 t.; Genoa, 60 t.

FERRO MANGANESE

Bilbao, 300 t.; Gothenburg, 60 t. 10 c.

GELATINE—

Esbjerg, 13 c.

LEAD SULPHATE—

Antwerp, 13 t.

MAGNESIUM CARBONATE—

Genoa, 15 t.

PITCH—

Gothenburg, 2 t. 16 c.

RED LEAD

Antwerp, 5 t. 8 c.; Gothenburg, 36 t. 3 c.; Genoa, 3 t. 2 c.; Rotterdam, 4 t., 18 c.

SOAP—

Antwerp, 9 t.; Bergen, 1 c.

SODA ASH—

Gothenburg, 434 t.

SODA CRYSTALS—

Rotterdam, 25 t.

SODIUM BICARBONATE—

Gothenburg, 10 t.

SODIUM SILICATE—

Gothenburg, 16 t. 5 c.

SODIUM SULPHATE

Gothenburg, 300 t.

SULPHUR—

Gothenburg, 10 t.

WHITE LEAD—

Antwerp, 17 t. 6 c.

N. & S. SHIELDS.

Week ending October 18.

NIL.

SWANSEA.

Week ending October 18.

NICKEL SULPHATE—

Antwerp, 10 cks., £120.; Rotterdam, 6 kgs., £300.

PRICES CURRENT.

THURSDAY, Oct. 23, 1919

PREPARED BY MESSRS. HIGGINBOTTOM AND CO., 21, SPRING GARDENS, MANCHESTER.

The values stated are F.O.R. at makers' works, or at usual ports of shipment in U.K., unless otherwise specified
The prices in different localities may vary.

Acids:—				£	s.	d.
*Acetic 40% and 60%	per cwt.	29/- & 44/-				
* " Glacial	per ton	85 0 0

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers) ...	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

CURRENT TOPICS.

GERMAN CHEMICAL INDUSTRY CONDITIONS.

FURTHER reports relating to the German chemical industry would appear to indicate that from the point of view of chemical manufacturers in that country prospects for the near future are anything but hopeful. The first report, emanating from the Verein zur Wahrung der Interessen der Chemischen Industrie, and presented at a recent general meeting of that body in Berlin, states that the chemical industry experiences a shortage of raw materials, particularly coal, while at the same time the coal delivered has greatly deteriorated; the ash content has risen from 12 to 15 per cent. formerly to as high as 35 per cent. at the present time. In addition there are great difficulties in the transport conditions on the railways and difficulties with the workmen. The final result has been, according to the report, that a number of the works in the west have been either partly or completely brought to a standstill, as, for instance, the works of Leopold Cassella and Co., Griesheim-Elektron, the Zellstoff Fabrik Waldhof, the Verein Chemischer Fabriken Mannheim, the Hoechst Farbwerke, and the Sodafabrik Wiehl, whilst the chemical works at Leverkusen are living from hand to mouth. As compared with this state of affairs the report remarks that an "immense hunger" for all kinds of chemical products prevails throughout the world, so that there would be an abundance of business if the German industry were able to work at full output. But even in this event it is said the Peace Treaty is against the development of the industry, as it takes away 50 per cent. of the existing stocks and 25 per cent. of the annual production until 1925. The position in regard to the markets in the late enemy countries is summed up as follows:—England, except by special permits, has prohibited the import of dyes and chemicals for a period of ten years; France has also issued import vetoes, and has imposed a duty of 6 francs per kilo. when permits are granted; and the United States has levied an *ad valorem* duty of 45 per cent. The report, in conclusion, expresses the opinion that the industry can only recover from the present depression by the greatest exertion of all forces, assiduity, and by proficiency. Equally gloomy are the conclusions of Mr. Irving A. Keene, chairman of the Advisory Committee on Drugs, Chemicals, and Dye-stuffs of the American Chamber of Commerce in London.

Mr. Keene has recently returned from a visit to Germany, and his impressions are published in the October *Bulletin* of the Chamber. Factories and workshops in the Rhineland towns which Mr. Keene visited are working for private German account, but are under the control of the occupying military authorities. Practically none of them could offer goods for export. Up to 50 per cent. of their output as in January, 1919, must be sold to the German Government for delivery to the Allies as indemnity, and little or nothing is left for export. All production, he says, is suffering from a serious lack of raw materials. Bayer and Co., for instance, had nothing to offer excepting a few vat colours, and could not sell anything without instructions from the Government. Colours other than vat colours were very scarce, and supplies of medicinal chemicals extremely low. At Frankfort, also, such big firms as Meister Lucius and Bruning and Cassella had practically nothing to offer. The former's place had been bombed, and they were able only to fill their orders and supply their fixed percentage to the Government for the Allies. At Darmstadt, E. Merck and Co. and the Griesheim Elektron had fine large plants but few materials for sale. The great demand is for raw materials, coal, and credit. Employers complain of a lack of energy on the part of the workmen. The proportion of productivity per man was quoted from as low as $33\frac{1}{3}$ per cent. to as high as 75 per cent. of the pre-war normal. Mr. Keene predicts, however, that this condition is a temporary one only. "Far from being in a position to dump dyestuffs and other chemicals on American, British, and other markets," asserts the writer, "Germany is actually short, and when she has delivered to the Allies the quantities required by the Peace Treaty there will be little left for export. The dire shortage of coal and raw materials precludes the possibility of her becoming anything more than a weak competitor for at least a year." Assuming that the above reports accurately represent the situation as it now exists in the German chemical industry, chemical manufacturers in this country would be well advised not to jump to the conclusion that matters are worse than they really are. By so doing the very grave danger would arise of a relaxation of the efforts that are being made to meet the competition of Germany in the future. In striking contrast to Mr. Keene's remarks anent the labour situation in Germany is the following quotation from the report of the Industrial Commission to Germany on the Wallpaper Industry: "A very outstanding feature was the alert and businesslike manner in which the staffs in all departments went about their work, and the grim determination of the employees, conscious of having lost the war, yet striving to win success in the industrial sphere by the quality and quantity of production." We quote the passage, not as a refutation of the conclusions of Mr. Keene, but simply for the purpose of drawing attention to the fact that the available information concerning industrial conditions in Germany, far from throwing a clear light upon matters tends to make them more obscure.

ALUMINIUM FROM LABRADORITE.

MR. L. HAWKES, writing in *Nature* (October 23), says that the metal aluminium can be obtained by electrolytic means from its oxide, and nearly all the suggested methods of manufacture depend upon this as a final stage, the main difficulty being the preparation of a sufficiently pure oxide, free from iron and silica. The ore commonly used is bauxite, after a rather costly preliminary purification by the Baeyer process. At the outbreak of war the Central Powers utilised their available bauxite, including the small deposits of poor quality in Germany; but the necessity for finding a more widespread source was felt, and a process was discovered and successfully put into operation by Dr. Buchner, of Heidelberg, for treating kaolin and kaolin-rich clays.

There is no bauxite in Norway, and it was first proposed to work the clays after the Buchner and other suggested methods. This, however, has for the most part proved impracticable owing to the unfavourable character of the clays, which are relatively unweathered glacial deposits, not only poor in alumina, 16-20 per cent., but with part of it bound in alkali feldspar, and therefore unavailable. In 1917, Prof. V. M. Goldschmidt, of the Mineralogical Institute, Christiania, conceived the idea of using labrador-stone as a source of aluminium. Labrador-stone is a white rock extensively developed in south-western Norway, and especially in the inner Sogne-fjord district. The main constituent of this rock is a plagioclase feldspar of the labrador group, the more felspathic varieties containing only a very small amount of iron-bearing pyroxenes, and with an alumina content of 30 per cent. Prof. Goldschmidt has found that the feldspar is surprisingly soluble in dilute acids, so that it can be dissolved out, leaving a residue of insoluble ferro-magnesian minerals and silica. The calcium and sodium oxides of the feldspar, 13 per cent. and 5 per cent. in amount respectively, go into solution with the alumina, and, using sulphuric acid, there is thus a considerable loss in the form of a useless by-product. This method is rejected for the manufacture of alumina, although it is used in the preparation of sufficient quantities of aluminium sulphate to satisfy Norwegian needs. By using nitric acid as a solvent, not only is a waste of acid avoided, but the precipitation with ammonia can be dispensed with—a valuable consideration in Norway, where ammonia cannot be obtained cheaply in quantity.

The main features of the process, which has been worked out by Prof. H. Goldschmidt, are as follows: The labrador-stone is extracted with dilute nitric acid, the 30 per cent. acid, first raw product of the electrical air-industry, serving for this purpose. The silica and greater proportion of the iron minerals remain insoluble, aluminium, calcium, and sodium going into solution together with a little iron. After removal of this iron the solution is evaporated down and the residue heated to a certain temperature at which the aluminium salt alone is decomposed, the nitric acid driven off being collected as a valuable concentrate. By washing with water the nitrates of calcium and sodium are removed, the alumina remaining.

This process seems to be full of promise for Norway—a country with such abundant water-power, a flourishing nitric acid industry, and an unlimited quantity of a raw material which few other countries possess; and hopes are entertained that a product will be obtained which will not only suffice for local needs, but also win a footing in the world's rapidly expanding aluminium market.

CHEMICAL ASPECTS OF THE POTASH INDUSTRY.

AT the opening meeting of the session of the Birmingham and Midland Section of the Society of Chemical Industry, held at the University of Birmingham on Thursday, October 23, an interesting paper by Mr. E. C. Rossiter, F.I.C., and Mr. Cyril S. Dingley, A.I.C., was read by the former on "Some Chemical Aspects of the Potash Industry in Great Britain." Dr. R. S. Morrell presided, in the absence of Mr. L. P. Wilson (the chairman of the Section), over a representative attendance.

It was announced that Dr. E. W. Smith, chief chemist at the Birmingham Gas Works, found himself unable, owing to pressure of engagements, to accept the position of chairman; and Mr. Wilson had consented to act in that position, and Dr. H. W. Brownson and Dr. Morrell had been elected vice-chairmen. Mr. J. C. Sheldon had been appointed representative and corresponding member of the Section on the Chemical Engineering Group.

The hon. secretary (Mr. F. R. O'Shaughnessy) stated that it was the intention of the Section to co-operate closely and sympathetically with the Group, which was very keen about developing its work. It had arranged for a conference to be held on April 22 on "Labour-Saving Devices in Chemical Works," and a number of interesting papers would be read. The contributions would include papers by American chemical engineers.

Mr. Rossiter, in the course of the paper, commented upon the importance of a home supply of potash, as being second only to that of the supply of combined nitrogen, both as regarded agriculture and industry. In the case of combined nitrogen the supply can, he pointed out, be obtained from synthetic processes, from by-product recovery, and from natural deposits. In the case of potash the last two sources only are possible. Potash occurred as a by-product in considerable quantities in the blast-furnaces, the cement industry, and the wool-washing industry. In 1917 there were some 240 blast-furnaces in blast in England and Wales, and the preliminary examination of each furnace for possible potash production took about seven days. They had, however, after three years' work, arrived at a stage when certain conclusions could be drawn as to the probable extent of potash production from this source.

BLAST-FURNACE DUSTS.

Unless certain modifications are made in the routine of blast-furnace management—namely, the simple addition of salt to the furnace charge combined with an adequate means of cleaning the furnace gases,—it is improbable that sufficient potash can be obtained to make a potash industry worth while. The greater portion of the potash charged into the furnace is carried into the slag; and the collection of the dust from the stoves and boilers will provide only a small portion of the potash requirements of the country, and then only of a very variable and inferior quality. An examination of materials used in the manufacture of pig-iron has shown that the chief source of the potash is the iron ore. Lime-stones and coals do not, as a rule, contain much more than 0.1 per cent. of potash stated as KCl, or about 3.5 lb. per ton of pig-iron made, but occasionally as much as 13-14 lb. per ton of pig is found in these constituents of the furnace charge.

Hundreds of analyses have been made to determine the potash contents of various flue-dusts from blast-

furnaces. Such dusts, provided they contain sufficient potash, and have been burnt in stoves or under boilers, can be used without further preparation in agriculture, and are therefore valuable as a source of potash. There is wide variation in the potash content, even when obtained from the same works. The heavy dust from the heavy dust-catcher and the flues near the furnace contains little potash; it varies from a trace to 2.05 per cent. of potash stated as KCl. On the other hand, the dust from stoves and boiler settings is usually valuable; the soluble potash varies from 3 per cent. K_2SO_4 with 4 per cent. KCl in the same sample to 30.5 per cent. K_2SO_4 . The potash insoluble in water varies from 3.6 to 11.4 per cent. stated as KCl, and soluble impurities such as sodium and calcium sulphates and chlorides also vary greatly. The following analysis may be taken as a fair sample of the dust obtained from the stoves of an ordinary blast furnace where no cleaning plant is installed: K_2SO_4 , 10.01 per cent. KCl, 1.60; NaCl, 1.14; $CaCl_2$, 1.18. Total soluble in water, 13.93 per cent.; SiO_2 , 26.49; Fe_2O_3 and Al_2O_3 , 37.46; CaO, 9.69; MgO, 1.98; PbO, 0.69; ZnO, 2.30; K_2O , 4.83; Na_2O , 0.55; CO_2 , 1.98 per cent.

The dust from stoves and boilers provides a very low potash content. The potash charged into the blast-furnace comes out either in the slag or in the gas. In the slag it probably occurs combined with silicates, and in the gas as a very fine fume, which, after cooling, may contain the potassium as carbonate, bicarbonate, formate, cyanide, thiocyanate, sulphate, and chloride, with small quantities of bromides and iodides. It usually contains a very constant quantity of chloride with varying quantities of carbonate and a smaller quantity of cyanides. It varies considerably for each works. This fume is so fine that a sample of the gas, if drawn into a hot aspirator, shows no signs of settling after remaining for several hours.

In those works which do not clean their gas most of the potash carried in the gas eventually escapes up the chimney after the gas is burnt at the boilers and stoves, and is evident in the white fume issuing. A small proportion is deposited with the heavy dust collected in the dust-catcher and the first portion of the gas main, and a larger proportion (but less than 10 per cent.) is deposited in the stoves and boiler flues, where, after the gas has been burnt, it is present as a mixture of sulphate and chloride.

For the manufacture of potassium salts only that portion of the potash which is carried by the gas is available, unless the small quantities of stove dust are collected for this purpose, and therefore when considering the distribution of potash it is of the first importance to determine the quantities of potash present in the gas and in the slag at every blast-furnace. The greater the quantity of potash present in the ores the greater is the proportion remaining in the slag. Unless a large proportion of the potash remaining in the slag can be transferred to the gas, a sufficient quantity of potash to make a potash industry worth while will not be available. The experiments show that by the simple addition of salt to the furnace charge a larger proportion of the potash is transferred from the slag to the gas. In regard to the ferro-manganese furnaces the whole of the potash is volatilised into the gas under normal working con-

ditions, and a large proportion is obtained as carbonate. The hæmatite furnace, using only foreign ores containing a small percentage of potash has, on the average, given an increase of 9lb. KCl for 13lb. of salt, and when the salt was more advantageously adjusted, an increase of 8.1lb. KCl for 9.2lb. of salt. When the salt is properly adjusted there is every prospect that 1lb. of KCl will be obtained for every pound of salt used. The basic iron furnace using 55-70 per cent. Cleveland ore mixed with foreign ores has, on the average, given an increase of 14.6lb. KCl per 37lb. of salt, or 1lb. KCl for each 2½lb. of salt used.

The Cleveland iron furnace using 94 per cent. Cleveland ore has, on the average, given an increase of 18.5lb. KCl per 37lb. of salt, or 1lb. KCl for each 2lb. of salt used. In both these furnaces the result is very similar. A substantial increase in the potash volatilised into the gas is obtained, but the potash in the slag cannot on the average be reduced to less than 1.0 per cent. KCl; that is, the greater portion of the potash remains in the slag. A larger quantity of salt will reduce the potash in the slag, although up to the present we have never obtained a satisfactory reduction; but with this larger quantity of salt the proportion of sodium chloride volatilised into the gas is so high that the separation of the sodium and potassium salts at the potash works is rendered more costly.

The authors believe this retardation of the action of salt in furnaces using Cleveland ores to be due to the low ratio of lime and magnesia to silica in the slags from these furnaces. Before salt is added the fume carried by the gas is neutral, and contains chlorides of calcium, iron, and aluminium, so that there is already present more than sufficient hydrochloric acid to combine with the potassium which is volatilised, but the low working temperature of the furnace may also retard the volatilisation of the potash.

The effect of adding salt on the dust collected in the cleaning plant is very marked; the salt addition has replaced a comparatively poor dust containing 15 per cent. of potash salt by one containing 26 per cent. KCl.

The authors are of opinion, from the results obtained by the addition of salt to those few furnaces to which it has been added up to the present, that in the case of furnaces using North Lincolnshire ores about 80 per cent. of the potash will be volatilised into the gas, and be therefore recoverable by the use of adequate gas-cleaning plant; the hæmatite furnaces will also yield about 80 per cent. of the potash, and the furnaces using Cleveland ores about 33 per cent. of the potash contained in the furnace charge. The analyses of ores shows Northamptonshire to have the highest average potash content, and on the information gained it appears that a potash industry obtaining raw material from the blast-furnaces of England and Wales will be able to provide potassium salt equivalent to 63,000 tons of potassium chloride per annum.

In this estimate no account of the potash now going to waste in the manufacture of ferro-manganese has been taken into account; neither has any allowance been made for the substitution of home ores for foreign ores. All factors considered, the authors are of opinion that a conservative estimate of the potash which can be recovered from the blast-furnaces of England and Wales may be taken at 80,000 tons per annum as KCl, equivalent to some 50,000 tons of potash expressed as K₂O, or more than double our pre-war requirements of potash.

DISCUSSION.

Dr. Morrell, in expressing the appreciation of the Section to the authors, said he believed the results obtained would be of great value to the community at large. He inquired whether the addition of the charge of salt interfered with the durability of the linings of the furnace, and Mr. Dingley replied that experience up to the present justified an answer in the negative.

Dr. Slater Price asked if, with war conditions over, potash produced by the process would be able to compete in cost with the supply that would be available from abroad.

Mr. Rossiter said there was no further expense, beyond apparatus, except that for salt added. Moreover, it was accepted generally by blast-furnace managers that it paid to clean the gas without considering the question of the cost of collecting the dust.

Mr. H. Silvester said with some knowledge of blast-furnace examination he was able to appreciate the enormous amount of detailed work that had been done. However this process of potash production might be regarded, the contribution of the authors to the literature of the subject would always be turned to with interest. It was essential that furnace-gas should be clean if it were to be used in gas engines. Furnace owners would welcome any information as to a cheap gas-cleaning apparatus.

Mr. F. C. A. H. Lantsberry said with the expansion of the pig-iron industry it was to be hoped that more and more furnace-gas would be used in gas engines, but it must be absolutely clean.

Dr. H. W. Brownsdon said the contribution was a noteworthy instance as to the value of by-products. It appeared to him that the time would come when the potash must be recovered from this source.

Mr. Rossiter suggested that it would pay to instal the necessary plant, because, apart from the production of potash, it would mean clean gas not only for gas engines, but for stoves and boilers. The question was one as to whether the country was going to stand still and continue to witness the enormous waste of power and fuel that now took place in our blast-furnaces. When the supply of potassium carbonate was stringent they produced it direct from the flue-dust. A very substantial amount of potash from the blast-furnaces was made each week at Oldbury.

CALCULATING LIQUID CONTENT OF TANKS.

THE storage of large quantities of liquids at chemical works in cylindrical tanks, usually in a horizontal position, while the liquids are frequently being added to or in part withdrawn, makes a ready method of measuring the contents at any time desirable. Tables to facilitate these calculations are given in hand-books, but they have the common defect of being applicable only to vessels of the diameters therein given; for other diameters the tables are useless. The author offers a formula which supplies the want. In this formula the value of the contents is a function of the radius and the height of the liquid. It is thus stated:—

$$V = \frac{V_0}{\pi} \left\{ \arccos \left(1 - \frac{h}{r} \right) - \left(1 - \frac{h}{r} \right) \sqrt{\frac{h}{r} \left(2 - \frac{h}{r} \right)} \right\}$$

where V_0 is the volume when the tank is full—i.e., the total capacity. It will be seen from the equation that the quotient $\frac{V}{V_0}$ is dependent only on the relation $\frac{h}{r}$. Hence it is applicable to any given diameter. This relation can be shown graphically, and the author gives a diagram which can be used in practice to save work in calculation.—*Chem. Zeit.*, April 3, 1919.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.—A general meeting of the society will be held on Tuesday next, November 4, at 5 p.m., when, an application having been received and approved by the Council for the formation of a chemical section of the society, the following resolution will be submitted to the meeting on behalf of the Council:—That the chairman and secretary of the chemical section of the society be added to the council as ex-officio members thereof."

DEVELOPMENT OF THE GERMAN CHEMICAL INDUSTRY.

FURTHER CONSOLIDATION OF INTERESTS AND CAPITAL INCREASES OF SEVERAL MILLIONS STERLING.

A GIGANTIC augmentation of share capital is now proposed to be carried into effect in the immediate future by the big companies engaged in the German heavy chemical industry—so enormous indeed that it throws entirely into the shade all previous expansions in capital made by any single industry at any former period. The scheme, as is claimed, shows the firm intention of the German companies also to maintain in the future the position which they acquired in the markets of the world as a result of work extending over many years.

It will be remembered that in 1916, as was reported in this journal at the time, the community of interests in the German aniline dye industry, which until then comprised only the Elberfeld Farbenfabriken of Leverkusen, the Badische Anilin und Sodafabrik of Ludwigshafen, and the A. G. für Anilin Fabrikation of Berlin-Treptow, was extended by the inclusion of the Farbwerke vorm. Meister Lucius and Brüning, of Höchst; Leopold Cassella and Co., of Frankfort-on-the-Main; Kalle and Co., of Biebrich; the Chemische Fabriken vorm. Weiler-ter-Meer of Uerdingen; and the Chemische Fabrik Griesheim-Elektron, of Frankfort-on-the-Main. The extended community excepted from its scope certain branches which were reserved exclusively for the firms at Ludwigshafen, Leverkusen, and Berlin, in so far as concerns the financing of the branches and the participation in the profits and losses resulting from them—that is to say, to the three firms forming the original community. This was specially the case with the nitrogen department. This branch has assumed considerable dimensions in the past few years, and has outgrown the capital resources of the companies concerned. So much so that it is estimated that the capital already invested in the works at Oppau and at Merseburg, and the considerable sum which is still required represent an amount of several hundred millions of marks. Under these circumstances it has been found necessary to widen the basis of the undertaking, and at the same time raise fresh capital.

It is computed that on the entire completion of the installations at Oppau and Merseburg, the plant will be able to produce 300,000 tons per annum of nitrate in the form of ammonia, ammonia sulphate, nitrate, etc., which would be supplied to German agriculture, and also be placed at the disposal of the chemical industry, and thus be able substantially to cover the inland requirements. It has now been agreed, however, to abandon particularly the reservation mentioned so as to bring about a simplification of the entire branch of working, and also enable all the firms to co-operate in the financing, and consequently in the financial results.

The scheme contemplates the doubling of their ordinary share capital by the three large firms at Leverkusen, Ludwigshafen, and Höchst by the issue of new shares; and the five other firms will also increase their capital in proportion to their percentage in the profits of the community. In addition each of the works will make an issue of preference shares to the extent of 40 per cent. of the amount of the increase in the ordinary capital. In this connection the directors of the Farbenfabriken vorm. Fried. Bayer and Co., of Leverkusen, announce that they

have decided, at an extraordinary meeting to be held on November 15, to recommend an increase in the ordinary capital by 90,000,000 marks, and in the preference capital by 72,000,000 marks. The ordinary shares, which will be entitled to participate in the results from January 1, 1920, will be taken over by a banking syndicate, and then will be offered to the shareholders. The preference shares are to be issued as "vinculum" registered shares, and to bear a preference interest at the rate of $3\frac{1}{2}$ per cent., and they will be taken over by the other firms in the community at the nominal value and be paid in cash to the extent of 25 per cent. The funds resulting to the companies by the issue of ordinary shares will serve to strengthen the working capital and to complete the Badische company's works at Oppau and Merseburg. On the other hand the Bayer Company states that the object of preference shares, which will not yield new capital to the community, is to serve the purpose of drawing closer together the bonds which connect the community, and thereby strengthen their competitive capability in the markets of the world.

The other two big companies which also have an ordinary share capital of 90,000,000 marks, are on the point of issuing similar statements. As far as concerns the remainder, the Chemische Fabrik Griesheim-Elektron has already convened a meeting for the same day, when a proposal will be submitted to raise the ordinary capital by 20,000,000 marks, and the preference by 18,000,000 marks, so that the total capital will be brought up to 63,000,000 marks. In the case of the Chemische Fabriken vorm. Weiler-ter-Meer the augmentation in the capital is to be 6,240,000 marks in ordinary and 6,656,000 in preference shares; and the other firms concerned are about to issue their proposals for raising further capital.

It is expected that all the new ordinary shares will be issued at the price of 107 per cent. It is intended to raise the capital, on account of the large amounts involved, in instalments in November or December, 1919, and in July and October, 1920.

SYNTHETIC NITRATES.

WHILE there is constant speculation going on in regard to the position and proportions of the synthetic nitrate industry in Germany, it is surprising how little attention is paid to the Norwegian developments in this direction. Thanks to the filip given to the enterprise by the war, it is understood that the Norwegian supplies of synthetic nitrate, manufactured by the electric-arc process, now reach an annual output of 150,000 to 200,000 tons. It is further known that plans are well advanced for harnessing more power and considerably augmenting the 300,000 to 350,000 H.P. which are at present used *in toto* at the works situated at Notodden and Rjukan.

The suggestion which is sometimes made that the artificial substances are not so valuable as the "real" ones is grossly misleading to the uninitiated. The products in question are really characterised by a high degree of purity. The Norwegian nitrate of soda, for example, is ordinarily of 96-98 per cent. purity, thus comparing favourably with the Chilean product, while it can be manufactured of approximately 99 per cent. purity. Nitrate of soda also complies with more or less similar standards. Nitrate of ammonia exceeds 99 per cent. in purity, testing about 34.8 per cent. nitrogen, while nitrate of lime is practically 98 per cent. pure, containing 13 per cent. nitrogen.

It may be of further interest to note that nitrate of lime, which has been exhaustively tested in this and other countries, has proved on the average of all the tests at least equal in efficiency, nitrogen for nitrogen, to the Chilean nitrate of soda. The proportion of lime which it leaves in the soil after the removal of the nitrate by the crop gives it an obvious additional value on soils poor in lime, and on heavy soils where the maintenance of a satisfactory tilth is an important factor.

Nitrate of ammonia by virtue of its high nitrogen content offers considerable attractions for export purposes, where freight is now the vital consideration. The field tests in this country conclusively show that its nitrogen is equally as efficient as that of the other high-grade nitrogenous fertilisers. The presence of practically one-half of its total nitrogen as ammonia is an important feature of nitrate of ammonia, rendering it a more gradually available source of nitrogen than a wholly nitrate product, and thus better adapted for certain crops and soils.

THE STRUCTURE OF COLLOIDS.

SOME time ago we described, says *Engineering*, how Debye and Scherrer had successfully applied Röntgen-ray examination to the study of the structure of crystalline and amorphous substances, in particular of graphite and amorphous carbon. That this X-ray examination was not limited to the investigation of the structure of crystals had indeed been demonstrated by M. von Laue and his collaborators in their first original researches.

In the *Nachrichten der Gesellschaft für Wissenschaften*, Göttingen, of last year (available so far in abstract only), P. Scherrer has extended the method to the examination of the structure of colloids, both organic and inorganic. The colloidal particle may or may not have a crystalline structure. In the former case the X-ray examination should yield interference bands arranged in a manner characteristic of the space lattice; the positions of the bands would not depend upon the size of the particles, but the breadth of the bands would depend upon the size. In the latter case, in the absence of a crystalline structure, there would be no distinct bands, only one or several maxima of interference in the region of the incident ray, and the interpretation of the observations, always a matter of difficulty, would be more intricate.

Examining colloidal gold and silver, Scherrer concludes that the particles are distinctly crystalline, and that they fit into the same space lattice as the microscopic crystals similarly studied; the deduced sizes of the particles, moreover, agree with those determined by other methods, with the aid of the ultramicroscope or of osmotic pressure measurements. Even the smallest gold particles, no longer discernible by the ultramicroscope, seemed to have the same space lattice. The gels of silica (and also of stannic acid), former experiments had proved, undergo structural changes in the course of time; the aged specimens now examined show the characteristics both of amorphous and of crystalline particles, and in such gels crystallisation is evidently proceeding. Typical organic colloids, such as albumen, casein, gelatine, starch, cellulose, on the other hand, appear to be truly amorphous, and their colloidal particles probably consist of individual molecules or of groups of irregularly orientated molecules.

PROPOSED AMENDMENTS TO TRADE MARKS LAW.

THE Association of British Chambers of Commerce have issued a statement showing the supplementary amendments to the Trade Marks Bill put forward by the Executive Council of the Associated Chambers. The Special Committee of the Associated Chambers met on October 15 and unanimously recommended amendments intended to ensure, for the more efficient protection of holders of trade marks, that a search for similarity shall be made before a mark is registered in Part B, the proposed new section of the register formed to facilitate the registration of British trade marks in other countries.

Other amendments proposed relate to trade marks of chemical substances and to the admission of documents of title as legal evidence, while a proposed new clause, to be added to the Bill after Clause 11, would enact that when considering applications for the registration of trade marks, or oppositions to trade marks, the Registrar may have regard to the possibility of confusion arising not only in the United Kingdom, but also outside the United Kingdom. It is pointed out that some of the reasons why a search ought to be made are that nearly all countries have a search for similarity; if there is no search, all registered holders will have to keep a look-out every week on the *Trade Marks Journal*, because opposition is their only defence; that it would be better for the applicant for a B trade mark that a search should be instituted, because otherwise he might find his mark registered, and then be faced with a lawsuit; if a mark is registered in Part B, which is identical or very similar to one in Part A, then infringement is practically legalised; a great many marks are registered in England by traders in the United States, and there are several other complications which might follow the omission of a search.

With regard to chemical substances, it is pointed out that in Clause 6 (2) of the Bill the words "any single chemical substance" are very vague, and it is thought that a person who obtains a word trade mark for a chemical substance ought not to suffer forfeiture of that trade mark unless he uses it in such a way as to prevent the public from being able to call the chemical substance by any other name.

The President of the Board of Trade announces that he has appointed a committee to consider:—(1) Whether any extension or amendment of the Merchandise Marks Act is required in respect of the provisions relating to indications of origin; (2) the utility and effect of national trade "marks" or other similar (collective) marks, and how far they should be authorised or encouraged in this country; (3) how far further international action may be necessary for the purpose of preventing the false marking of goods. The secretary is Mr. M. F. Levey, of the Industrial Property Department of the Board of Trade, and all communications on the subject of the committee should be addressed to him at the Patent Office, 25, Southampton Buildings, W.C. 2.

FLAMELESS POWDER.—At a recent meeting of the French Academy of Sciences in Paris, M. Depech gave an account of experiments on the effect of adding charcoal, vaseline, and other substances to propellant explosive from the point of view of producing a flameless explosion at the gun. Vaseline and heavy petroleum oil proved to be the most effective, provided that suitable additions to the weight of the charge were made to make up for the addition of the non-explosive material.

BRITISH OVERSEAS CHEMICAL TRADE IN 1918.

(Continued from page 449.)

WE give below extracts from the annual statement, just issued, of the trade of the United Kingdom with foreign countries and British Possessions in 1918, compiled by the Customs and Excise Department. The figures relating to the chemical and allied trades will be found much more useful than those given in the monthly Board of Trade returns, owing to the detailed analysis of the countries of origin of imported, and the destinations of exported, chemical products. Each product is specified separately, together with the extent of the trade done with the more important countries, the corresponding figures for 1917 being in parentheses.

EXPORTS.

Muriate of Ammonia.—Russia, — (2,662cwt.); Sweden, — (19cwt.); France, 16,020cwt. (14,743cwt.); Spain, 347cwt. (1,995cwt.); Italy, 5,199cwt. (7,977cwt.); Turkey, 40cwt. (70cwt.); Japan, 75cwt. (6,941cwt.); United States, 2,269cwt. (19,684cwt.); other foreign countries, 4,166cwt. (5,368cwt.); Egypt, 6,779cwt. (3,929cwt.); British India, 4,983cwt. (11,324cwt.); Australia, 1,167cwt. (1,466cwt.); Canada, 1,734cwt. (3,887cwt.); other British Possessions, 1,427cwt. (4,459cwt.); total, 44,206cwt. (84,524cwt.).

Saltpetre (Nitrate of Potash), British Prepared.—Denmark, — (160cwt.); Portugal, 2,282cwt. (257cwt.); Italy, 400cwt. (1,403cwt.); Brazil, 3,416cwt. (748cwt.); Argentine Republic, 7,802cwt. (5,261cwt.); other foreign countries, 365cwt. (691cwt.); Australia, 22cwt. (262cwt.); other British Possessions, 2,169cwt. (1,153cwt.); total, 16,456cwt. (9,935cwt.).

Chromate and Bichromate of Potash.—France, 8cwt. (1cwt.); other foreign countries, 19cwt. (33cwt.); Egypt, 3,186cwt. (3,407cwt.); British East Indies, 587cwt. (3,786cwt.); Australia, 73cwt. (134cwt.); Canada, 139cwt. (158cwt.); other British Possessions, 322cwt. (259cwt.); total, 4,334cwt. (7,778cwt.).

Potash Compounds, Other Sorts.—Russia, — (£7,884.); Germany, — (£2,928.); France, £2,578. (—); China, — (£60.); Japan, £10. (£8.); United States, £489. (£1,000.); Brazil, £9,785. (£6,386.); other foreign countries, £3,702. (£3,033.); South Africa, £3,163. (£9,096.); British India, £2,634. (£8,328.); Australia, £4,595. (£4,410.); Canada, £2,064. (£6,080.); other British Possessions, £3,903. (£5,180.); total, £32,923. (£54,393.).

Soda Ash.—Russia, — (41cwt.); Sweden, 1,308cwt. (900cwt.); Norway, 424,301cwt. (364,328cwt.); Netherlands, 107,558cwt. (160,169cwt.); France, 433,472cwt. (305cwt.); Italy, 179,001cwt. (220,642cwt.); Turkey, 900cwt. (400cwt.); China, 192,844cwt. (229,493cwt.); Japan, 506,994cwt. (409,329cwt.); United States, — (8,472cwt.); Brazil, 105,473cwt. (71,879cwt.); Argentine Republic, 212,440cwt. (148,122cwt.); other foreign countries, 70,370cwt. (139,591cwt.); Egypt, 24,895cwt. (22,226cwt.); British South Africa, 36,314cwt. (49,508cwt.); British India, 553,958cwt. (766,891cwt.); Australia, 274,277cwt. (319,778cwt.); New Zealand, 49,126cwt. (38,713cwt.); Canada, 165,258cwt. (220,195cwt.); other British Possessions, 39,659cwt. (34,460cwt.); total, 3,378,148cwt. (3,205,442cwt.).

Soda, Bicarbonate.—France, 51,301cwt. (68,588cwt.); Italy, 40,615cwt. (41,622cwt.); China, 5,079cwt.

(4,159cwt.); Japan, 44,627cwt. (56,304cwt.); Brazil, 7,866cwt. (9,926cwt.); Argentine Republic, 11,081cwt. (25,705cwt.); other foreign countries, 19,305cwt. (36,127cwt.); Egypt, 1,545cwt. (5,150cwt.); British South Africa, 14,432cwt. (10,521cwt.); Bombay (including Karachi), 41,375cwt. (42,048cwt.); Madras, 11,505cwt. (7,894cwt.); Bengal, Assam, Bihar, and Orissa, 33,021cwt. (42,370cwt.); Burmah, 12,153cwt. (14,381cwt.); Western Australia, 3,018cwt. (3,474cwt.); South Australia, 4,699cwt. (3,898cwt.); Victoria, 26,468cwt. (16,994cwt.); New South Wales, 38,786cwt. (41,362cwt.); Queensland, 3,693cwt. (3,793cwt.); Tasmania, — (175cwt.); New Zealand, 21,779cwt. (6,908cwt.); Canada, 18,553cwt. (37,604cwt.); other British Possessions, 27,547cwt. (20,617cwt.); total, 438,848cwt. (499,620cwt.).

Soda, Caustic.—Russia, — (4,393cwt.); Sweden, 301cwt. (—); Norway, 1,969cwt. (9,192cwt.); Netherlands, 32,536cwt. (39,816cwt.); Java, 6,022cwt. (1,355cwt.); France, 39,779cwt. (9,849cwt.); Switzerland, 27,932cwt. (11,116cwt.); Portugal, 11,070cwt. (254cwt.); Italy, 113,604cwt. (178,421cwt.); China, 7,544cwt. (191cwt.); Japan, 11,418cwt. (2,110cwt.); United States, — (21cwt.); Mexico, 603cwt. (—); Chili, 5,119cwt. (639cwt.); Brazil, 64,781cwt. (10,322cwt.); Uruguay, 14,470cwt. (1,683cwt.); Argentine Republic, 46,956cwt. (13,703cwt.); other foreign countries, 19,874cwt. (5,681cwt.); Egypt, 8,815cwt. (14,413cwt.); British South Africa, 59,695cwt. (27,886cwt.); Bombay (including Karachi), 24,861cwt. (34,596cwt.); Madras, 6,404cwt. (5,997cwt.); Bengal, Assam, Bihar, and Orissa, 24,238cwt. (39,997cwt.); Burmah, 1,508cwt. (1,284cwt.); Western Australia, 1,351cwt. (1,369cwt.); South Australia, 2,795cwt. (3,073cwt.); Victoria, 28,190cwt. (10,254cwt.); New South Wales, 46,328cwt. (12,843cwt.); Queensland, 7,594cwt. (1,173cwt.); Tasmania, 101cwt. (16cwt.); New Zealand, 12,984cwt. (4,918cwt.); Canada, 1,994cwt. (20cwt.); other British Possessions, 10,293cwt. (4,922cwt.); total, 641,129cwt. (451,507cwt.).

Sodium Chromate and Bichromate.—France, 53,960cwt. (62,731cwt.); Switzerland, 2,397cwt. (671cwt.); Spain, — (20cwt.); Italy, 7,922cwt. (5,093cwt.); other foreign countries, 1,568cwt. (428cwt.); British India, 7,518cwt. (16,753cwt.); Australia, 6,199cwt. (6,692cwt.); Canada, 1,695cwt. (3,560cwt.); other British Possessions, 434cwt. (1,582cwt.); total, 81,693cwt. (97,530cwt.).

Soda Crystals.—Netherlands, — (10,173cwt.); France, 50cwt. (13,750cwt.); United States, 500cwt. (230cwt.); Chili, — (619cwt.); Argentine Republic, 53cwt. (13,702cwt.); other foreign countries, 528cwt. (5,710cwt.); Malta and Gozo, 1,937cwt. (2,456cwt.); Cape of Good Hope, 36cwt. (2,059cwt.); British India, 1,660cwt. (9,928cwt.); Canada, — (1,952cwt.); other British Possessions, 9,204cwt. (21,524cwt.); total, 13,968cwt. (82,103cwt.).

Soda, Sulphate (Saltcake).—Norway, 157,013cwt. (117,362cwt.); Netherlands, — (21,210cwt.); Spain, — (186cwt.); Italy, 900cwt. (6,000cwt.); Brazil, 125,601cwt. (47,383cwt.); other foreign countries, 5,109cwt. (30,695cwt.); total, 591,427cwt. (414,726cwt.).

Soda Compounds, Other Sorts.—Russia, — (4,853cwt.); Netherlands, 24cwt. (833cwt.); France, 117,307cwt. (43,977cwt.); Switzerland, 21,718cwt. (17,711cwt.); Portugal, 30,657cwt. (27,910cwt.); Spain, 10,179cwt. (19,458cwt.); Italy, 133,182cwt. (150,782cwt.); Greece, 14cwt. (10cwt.); Turkey, —

933cwt. (—); Japan, 14,740cwt. (16,708cwt.); United States, 9,021cwt. (23,038cwt.); Mexico, 11,977cwt. (1,698cwt.); Chili, 8,852cwt. (3,017cwt.); Brazil, 28,188cwt. (21,650cwt.); Argentine Republic, 43,985cwt. (56,255cwt.); other foreign countries, 40,585cwt. (25,458cwt.); Cape of Good Hope, 7,273cwt. (7,161cwt.); Natal, 11,710cwt. (9,286cwt.); British East Indies, 28,660cwt. (50,881cwt.); Australia, 40,854cwt. (38,595cwt.); New Zealand, 17,373cwt. (14,122cwt.); Canada, 10,959cwt. (9,436cwt.); other British Possessions, 18,543cwt. (16,427cwt.); total, 606,734cwt. (559,266cwt.).

Soda Compounds, Total.—Russia, — (9,389cwt., valued at £113,158.); Sweden, 1,610cwt., £1,345. (2,702cwt., £1,596.); Norway, 586,307cwt., £143,722. (498,501cwt., £87,444.); Netherlands, 141,584cwt., £110,033. (241,710cwt., £135,399.); Java, 13,314cwt., £16,060. (14,449cwt., £9,689.); Belgium, — (710cwt., £235.); France, 696,609cwt., £641,037. (199,200cwt., £278,843.); Portugal, 49,174cwt., £49,220. (31,870cwt., £17,967.); Spain, 10,673cwt., £15,150. (20,041cwt., £17,178.); Italy, 475,503cwt., £446,462. (604,344cwt., £499,453.); Roumania, — (403cwt., £358.); Turkey, 2,113cwt., £1,250. (550cwt., £417.); China, 220,702cwt., £69,632. (240,181cwt., £67,688.); Japan, 577,784cwt., £182,886. (484,490cwt., £144,523.); United States, 10,312cwt., £49,695. (55,650cwt., £36,471.); Mexico, 21,555cwt., £13,285. (2,117cwt., £772.); Chili, 36,683cwt., £23,311. (21,450cwt., £9,670.); Brazil, 331,909cwt., £211,527. (161,546cwt., £73,072.); Uruguay, 47,161cwt., £36,028. (30,598cwt., £13,688.); Argentine Republic, 316,159cwt., £183,243. (257,714cwt., £119,415.); other foreign countries, 106,724cwt., £179,500. (156,554cwt., £104,454.); South Africa, 131,944cwt., £154,111. (111,372cwt., £77,835.); Bombay (including Karachi), 228,249cwt., £134,124. (259,974cwt., £181,753.); Madras, 73,059cwt., £38,661. (53,213cwt., £50,975.); Bengal, Assam, Bihar, and Orissa, 389,342cwt., £139,216. (668,402cwt., £223,782.); Burmah, 45,692cwt., £17,226. (36,201cwt., £13,446.); Western Australia, 11,970cwt., £7,513. (12981cwt., £5,445.); South Australia, 29,967cwt., £14,375. (30,183cwt., £10,784.); Victoria, 184,699cwt., £122,598. (183,554cwt., £79,456.); New South Wales, 229,873cwt., £147,204. (203,282cwt., £79,651.); Queensland, 27,709cwt., £20,539. (33,203cwt., £12,063.); Tasmania, 1,559cwt., £720. (1,262cwt., £479.); New Zealand, 101,497cwt., £63,521. (65,865cwt., £33,650.); Canada, 499,042cwt., £119,040. (462,923cwt., £106,672.); other British Possessions, 151,469cwt., £124,668. (153,610cwt., £124,473.); total, 5,751,947cwt., £3,476,902. (5,310,194cwt., £2,631,954.).

Sulphuric Acid.—Switzerland, 11,166cwt. (12,609cwt.); other foreign countries, 1,583cwt. (660cwt.); Egypt, 5,053cwt. (757cwt.); Bombay (including Karachi), 23cwt. (78cwt.); Madras, 2cwt. (8cwt.); Bengal, Assam, Bihar, and Orissa, 41cwt. (227cwt.); Burmah, — (38cwt.); other British Possessions, 4,863cwt. (6,270cwt.); total, 22,731cwt. (20,647cwt.).

Tartaric Acid.—Russia, — (1,136cwt.); Netherlands, 16cwt. (501cwt.); Spain, — (755cwt.); Japan, 20cwt. (1,123cwt.); United States, 40cwt. (1,106cwt.); Argentine Republic, — (2,301cwt.); other foreign countries, 204cwt. (915cwt.); Australia, 1,183cwt. (6,065cwt.); Canada, 447cwt. (1,982cwt.); other British Possessions, 1,105cwt. (1,550cwt.); total, 3,015cwt. (17,434cwt.).

Chemicals and Chemical Preparations, Unenumerated.—Russia, — (£288,635.); Sweden, £4,576. (£12,885.); Norway, £209,286. (£151,274.); Denmark, £8,563. (£15,265.); Netherlands, £16,617. (£61,027.); Belgium, £21. (£13.); France, £668,584. (£674,724.); Portugal, £30,716. (£25,201.); Portuguese East Africa, £952. (£3,530.); Spain, £80,497. (£58,192.); Italy, £1,036,971. (£299,521.); Turkey, £975. (£251.); China, £16,419. (£23,407.); Japan, £100,396. (£162,731.); United States, £109,483. (£128,406.); Mexico, £2,456. (£892.); Chili, £3,406. (£8,118.); Brazil, £40,620. (£28,318.); Uruguay, £1,397. (£769.); Argentine Republic, £53,182. (£46,877.); other foreign countries, £88,500. (£90,398.); Egypt, £27,444. (£20,214.); Cape of Good Hope, £78,005. (£30,543.); Natal, £43,476. (£24,651.); Transvaal, £67,080. (£21,377.); Bombay (including Karachi), £191,680. (£280,738.); Madras, £17,207. (£12,369.); Bengal, Assam, Bihar, and Orissa, £38,733. (£37,839.); Burmah, £14,320. (£17,936.); Straits Settlements, £17,580. (£13,261.); Hong Kong, £7,395. (£5,424.); Western Australia, £9,994. (£14,046.); South Australia, £14,304. (£8,124.); Victoria, £79,161. (£70,617.); New South Wales, £104,108. (£79,457.); Queensland, £19,928. (£19,438.); Tasmania, £545. (£669.); New Zealand, £50,977. (£48,584.); Canada, £55,218. (£46,747.); British West Indies, £14,249. (£13,960.); other British Possessions, £49,013. (£52,749.); total, £3,374,034. (£2,899,177.).

Chemicals, Etc., Total.—Russia, — (£952,807.); Sweden, £12,071. (£28,002.); Norway, £412,768. (£412,677.); Denmark, £9,025. (£58,532.); Netherlands, £202,342. (£272,472.); Java, £29,064. (£27,760.); Belgium, £21. (£248.); France, £5,814,228. (£4,944,366.); Portugal, £256,727. (£149,244.); Portuguese East Africa, £22,022. (£28,603.); Italy, £2,011,898. (£1,435,152.); Spain, £318,868. (£145,967.); Greece, £35,162. (£532.); Roumania, — (£855.); Turkey, £3,208. (£1,417.); China, £105,560. (£106,822.); Japan, £633,868. (£465,399.); United States, £506,961. (£663,407.); Cuba, £13,375. (£5,808.); Mexico, £216,614. (£142,747.); Chili, £71,813. (£40,071.); Brazil, £433,237. (£232,206.); Uruguay, £61,830. (£28,912.); Argentine Republic, £526,092. (£382,665.); other foreign countries, £1,156,151. (£941,736.); Egypt, £257,894. (£170,264.); British West Africa, £39,112. (£53,599.); Cape of Good Hope, £318,684. (£301,495.); Natal, £277,060. (£232,464.); Orange Free State, £1,451. (£1,330.); Transvaal, £565,065. (£604,690.); Bombay (including Karachi), £670,867. (£928,345.); Madras, £128,176. (£143,998.); Bengal, Assam, Bihar, and Orissa, £293,268. (£395,708.); Burmah, £44,647. (£48,548.); West Australia, £116,464. (£132,198.); South Australia, £36,032. (£33,325.); Victoria, £336,624. (£306,724.); New South Wales, £334,160. (£286,542.); Queensland, £59,944. (£53,335.); Tasmania, £4,564. (£4,858.); New Zealand, £252,333. (£209,536.); Canada, £370,565. (£416,355.); other British Possessions, £328,898. (£321,849.); total, £17,288,713. (£16,113,570.).

China Clay.—Netherlands, 1,056 tons (4,526 tons); France, 37,766 tons (29,436 tons); Italy, 8,288 tons (15,253 tons); United States, 152,383 tons (213,851 tons); other foreign countries, 6,211 tons (8,557 tons); British India, 20,264 tons (25,903 tons); Canada, 6,365 tons (13,016 tons); other British Possessions, 131 tons (208 tons); total, 232,464 tons (310,750 tons).

(To be concluded.)

CHEMICAL WORKS LAYOUT.

AT the College of Technology, Manchester, on Tuesday, the second and concluding lecture was given by Mr. John Allan on "Site, Layout, and Construction of Chemical Plant." The first lecture, which was reported in our last issue, was devoted to a careful consideration of the conditions which influence the choice of a suitable site for the erection of a chemical works. The present lecture was concerned chiefly with the gravitation and level-flow systems of arranging the processes used, the former having the great advantage of requiring a considerably smaller ground area for the necessary buildings. Where the primary raw materials employed in the process were in liquid form, or in the form of solutions, the gravitation-flow system was well suited, as the materials could be easily transported to the top storey of the building, and permitted to pass by gravitation for treatment in the different stages of manufacture. Such a system of flow was less suitable than the level-flow system if the raw materials were of a heavy nature, if the process of manufacture was complicated and involved, or if the materials in passing through the process were subjected to much handling. Moreover, where large units of plant were required, as was the case in many processes employed in chemical works, the level flow system was essential. In arranging the layout of a chemical works very great facility was offered where only one product was being made, and as an illustration of this, Mr. Allan described in detail the layout of a plant for the extraction of aluminium oxide from bauxite. Where the operations were more complicated, and a series of processes was being carried out, as in the manufacture of dyes and the like, the layout of the works was a much more difficult matter. In concluding his lecture, Mr. Allan referred to the means to be adopted for conducting water, steam, etc., through the works. The mains should be easily accessible, and should be carried either alongside the walls, supported by brackets, or along bridges. Leakage of material could then be discovered at once.

EXPORT LICENCES FOR OIL-SEEDS.

THE Colonial Office has made it known that the Governments of Nigeria, the Gold Coast, Sierra Leone, and the Gambia have been requested, at the instance of the Food Controller, to prohibit the exportation from those colonies during the next few months to all destinations outside the British Empire of palm kernels, ground nuts, and copra, but to issue export licences to all exporters of those articles to the United Kingdom who apply for them on the following basis:—

(a) The licence to be transferable by the holder if desired, and to authorise the exportation to any country outside the British Empire to which goods may lawfully be exported of a fixed proportion of the amount of the article which that exporter has shipped to the United Kingdom.

(b) The proportions to be:—Palm kernels, a licence for 10 tons for every 90 tons shipped to the United Kingdom; ground nuts, a licence for 20 tons for every 100 tons shipped to the United Kingdom; copra, a licence for 100 tons for every 100 tons shipped to the United Kingdom.

It has been left to the discretion of the colonial Governments whether they should adopt the above arrangements as regards ground nuts pending receipt of information as to whether the Indian Government intend to impose

restrictions on the exportation to destinations outside the Empire of Indian ground nuts. When the above-mentioned export prohibitions have been imposed, other oil-seeds and oleaginous nuts, seeds, and products (with the possible exception of palm kernel oil) will be freed from export prohibitions in the British West African colonies and protectorates.

Under these arrangements the granting of export licences to exporters will be entirely a matter for the colonial Government, to whom all applications should be addressed.

STANDARDISATION OF ZINC CONTRACTS.

H.M. ACTING COMMERCIAL SECRETARY at Washington states that a movement has been started by the American Zinc Institute to establish a uniform standard contract on zinc sales. It is pointed out that the immediate object of the contract is the necessity to have covered in the contract the date by which shipping instructions must be given for the month's deliveries. Of late, it has been said, a great deal of trouble was caused by buyers not sending shipping directions during the month. The contract called for delivery to be made, and in consequence some sellers have claimed by such a failure that the buyer has forfeited his right to receive the metal.

The American Zinc Institute suggests that the most explicit form of contract is that which is used by the American Metal Company, and which, in part, reads as follows:

Quantities for which specifications have not been received by the 10th of the month during which shipment is to be made, are to be forwarded only as soon as convenient to the sellers after receipt of such specifications.

Subject to strikes, fires, floods, wars, delays in transportation, and all other causes beyond the control of either party; this contract to be deemed suspended so long as such causes prevent or delay its execution.

Each shipment to be considered a separate sale. Payment to be made in New York Exchange, and, if not made in accordance with the terms herein, sellers have the option of cancelling all undelivered quantities.

The secretary of the Institute, in drawing the attention of the various members of the Zinc Institute to the proposed standard form of contract, points out that it is needless to relate the great advantages that would result through having a single form of contract used through the zinc trade, in which buyers' and sellers' rights are distinctly set forth, and would prevent numerous misunderstandings and arguments that occur at present, and would further be in line with standardising and stabilising the industry.

It is also pointed out that the contract should contain:

(1) An analysis of the different grades of zinc.
(2) It should state the tons, unless stated to the contrary, to be 2,000 pounds each.

(3) It should state within what period of time the zinc would have to be shipped if sold for prompt shipment.

(4) By what date shipping instructions should be given for shipments to be made during that month, and in that connection the 20th day of the month is deemed suitable for zinc. (On copper contracts shipping instructions and specifications must be in by the 10th day, as copper has to be made up in special

forms, and therefore it is pointed out it is necessary to receive instructions earlier than in the case of zinc.)

(5) It should carry a strike clause, covering not only strikes, but all other contingencies beyond the seller's control.

(6) The payments should be made payable in New York Exchange or its equivalent.

SOCIETY OF CHEMICAL INDUSTRY.

NEWCASTLE-ON-TYNE SECTION.

THE first meeting of the winter session of the above section was held on Monday in the Armstrong College, Professor Bedson presiding. An address was given by Professor W. A. Bone, F.R.S., on the

"British Association Fuel Economy Committee's Second Report."

Professor Henry Louis opened the discussion by remarking that he was in rather an awkward position in discussing a report to which he was a party. The broad conclusion that production was falling off was one they could not get away from. The reasons were many and complex. Personally, he considered that the Minimum Wage Act had had a serious effect on output. It had been described by a North-country miner as: "The minimum wage is what you get for going down, and if you want more you have to work for it." That Act, coupled with the recent rises in wages, had had an effect on output. It was not that the men were not capable of working, or that our seams were being rapidly exhausted. Until the present minimum wage system was remedied we were not likely to do much better. The outlook was exceedingly grave. We were faced with a gradual diminution of output because we were the oldest coal-producing country, with the result that our best and easiest worked seams were being worked out, and we had to work thinner and poorer seams. He thought Professor Bone had suggested that output could be increased by the use of more machinery, as in America. He (Professor Louis) did not believe it. He believed there were very few places in the country where coal-cutting machinery might be introduced in which it was not already in operation to-day. The only thing was to get a healthy feeling among the coal-producers; to get the coal-producers to see that it was to their advantage, and to the advantage of the nation at large, that they should do as much as possible instead of as little as possible. To increase the output and economise on the product were the two great coal problems they had got to solve.

Dr. J. T. Dunn said he agreed with Professor Bone on decentralisation, and held that whatever Government money was spent on research should not be confined to the central official organisation. He believed that Professor Bone had spoken wisely in saying that all the technical knowledge of the country ought to be brought to bear on the fundamental investigation of the constituents of coal and a survey of the whole coalfield of the country. He did not think that a central body could hope to get the work done—that was, a practical survey of every coal seam in the kingdom. A great deal of investigation was necessary before the recommendations of the Fuel Board should be carried out.

Mr. T. Hardie said if one industry was dealing economically with coal it was the gas industry. It seemed to him an extraordinary thing that a committee of scientific gentlemen, after four years in which gas undertakings had supplied gas of all qualities which had shown no signs of danger in using and which had been reasonably usable, should suggest restrictions upon gas

managers based upon what they themselves put forward as a national policy.

Dr. J. E. Paterson said that he could not speak as a gas engineer, but, in common with all chemists, he had felt badly handicapped by want of knowledge of our own coal. It was almost impossible to go to buying departments and ask for certain coal because it was most suitable for a certain purpose, because they did not yet know sufficient about it. He felt the necessity for a long and exhaustive research on the fundamental properties of coal. That centralisation in investigation was a mistake he was certain. Different points of view were very necessary in arriving at the truth.

DYESTUFFS SUPPLIES.

IN reply to their letter to the Board of Trade urging that steps should be taken to secure an adequate supply of dyewares for the woollen and other industries, the Batley and Birstall Chamber of Commerce have received a letter from the Board, which says:—"The Board fully appreciate the necessity for securing a supply of such essential dyestuffs as are unobtainable in sufficient quantities from British sources of manufacture, and with this object in view are making arrangements, which it is hoped will be completed in the near future, for securing an interim supply of such dyestuffs from Germany under the terms of the peace treaty. An announcement as to these dyestuffs and the manner in which they will be available to consumers will shortly be made."

At Wednesday's meeting in London of the Associated Chambers of Commerce, the following resolution was moved by the Dewsbury Chamber, and seconded by Batley and Birstall:—"That this Chamber demands the immediate removal of all restrictions on the introduction of dyestuffs and the abolition of the Licensing Sub-Committee appointed by the Board of Trade to control such imports; or representation on such committee of smaller manufacturers, of merchants, and of the independent consumers."

The Select Committee on High Prices and Profits met on October 23 to consider what further action should be taken.

According to the London correspondent of the *Manchester Guardian* Major Barnes intimated his desire to secure from Sir Auckland Geddes an explanation of the contradiction that apparently exists between the statement made by him when giving evidence before the Select Committee that the Government had, when taking shares in the British Dyestuffs Corporation to the amount of £1,700,000., attached a provision limiting the profits of the company, and the fact that no such provision appears on the prospectus of the British Dyestuffs Corporation.

What seems to have taken place is that an agreement was made between the Board of Trade and the British Dyestuffs Corporation by which the Government undertook to lend the company £1,700,000., the loan being secured by a debenture and accompanied by a restriction of the dividend to 8 per cent. For some reason or other this agreement, after being duly completed by all the parties and ratified by the company, was set aside and the money applied to the purchase of shares in the company, such purchase having no conditions limiting dividends attached to it. There is clearly some discrepancy between the statements made by Sir Auckland Geddes in his evidence and the facts ascertained, and it would be interesting to learn what explanation Sir Auckland Geddes has to give.

ITEMS OF INTEREST.

BOGUS SUBSTITUTE FOR OLIVE OIL.—For selling an olive oil substitute which on analysis was found to be refined paraffin artificially coloured with an organic dye, a grocer at Fakenham, Norfolk, was fined £5.

IMPORTS OF FERTILISERS INTO FINLAND.—The Finnish Commercial Attaché in London has notified the Board of Trade that the restrictions on the importation of fertilisers into Finland have been removed.

DUTCH OIL AND SOAP INDUSTRIES.—We learn that the Dutch periodical *Olie en Vetten*, a technical and economic weekly for the Netherlands and Colonies, will be considerably enlarged with respect to information concerning oil, fat, soap, paints, and allied products.

SALE OF THE LATE SIR WILLIAM CROOKES' LIBRARY. As will be seen from our advertisement columns, Messrs. Hodgson and Co., of 116, Chancery Lane, London, W.C., will sell by auction on Thursday and Friday, November 13 and 14, the valuable and extensive library of the late Sir William Crookes, O.M., F.R.S.

RHODESIA MINERAL OUTPUT.—The British South Africa Company announces the following mineral output from Southern Rhodesia during September:—Gold, 53,021oz.; silver, 13,632oz.; coal, 43,139 tons; chrome ore, 1,816 tons; copper, 253 tons; asbestos, 934 tons; arsenic, 18 tons; diamonds, 31 carats. The number of producers is 142 and the value of the gold produced £223,719.

SPECIFIC GRAVITY OF ETHYLENE.—There have been great doubts as to the specific gravity of ethylene gas. The figures obtained by different experimenters have differed considerably from one another. M. T. Batuceas has determined it afresh, and found a new value 0.9749 times the specific gravity of air. This figure brings out the atomic weight of carbon as 11.996, 11.999, 12.005, or an average of 12.000.—*Gas World*.

INDIA AND AMERICAN DYES.—Representations made by the American Chamber of Commerce in London have resulted in the Government of India instructing their Customs officers to admit freely into India prohibited dyes and dyestuffs ordered before September 6 from other than ex-enemy countries, and shipped before January 1 next. The Australian Government, a few months ago, granted a period of grace amounting to 3½ months.

POTASH RECOVERY FROM CEMENT DUST.—Several Portland cement factories in the United States which have installed plant for the recovery of potash from their flue dust are said to have recouped the capital costs during the first year of working. In 1917, about 45 per cent. of the total production of potash was derived from brines, about 10 per cent. from kelp, nearly 9 per cent. from charred molasses residues, and about 5 per cent. from cement mills. Cement mill production of potash in 1918 was equivalent to 1,429 tons of pure potassium oxide.

GERMAN TAR INDUSTRY AND PEACE CONDITIONS.—The Tar Producers' Union in Germany writes to the *Kölnische Zeitung* that according to the peace treaty Germany must deliver 50,000 tons of coal-tar a year to the Entente countries. On the top of this it is probable that as a consequence of transfer of territory a considerable percentage of German coal-production, and therewith tar-production, will fall short. That means that owing to the small production of coal there will be a great decline in the production of tar. The German tar industry is not in a position to supply the inland requirements in tar products. The economic use of the quantities of tar still available is therefore an absolute necessity, along with a concurrent increase in the production of tar.

ASBESTOS PRODUCTION IN QUEBEC.—According to the report of the Quebec Bureau of Mines the production of asbestos in the province reached a new high record in 1918, and the industry is in a highly prosperous state. Both the tonnage and the value of the product exceeded all previous records. Asbestos in the shape of "crude" and "mill-stock," was shipped to the amount of 142,375 short tons, to which is to be added 16,850 tons of "asbestic," a by-product of low price, or in all a total tonnage of 159,225. The value of the asbestos proper was \$9,019,899., or with the "asbestic" \$9,053,945. As compared with the previous year's figures, 154,452 tons valued at \$7,240,697., this shows an increase of 4,773 tons, or 3.1 per cent. in quantity, and \$1,779,202., or 24.5 per cent. in value.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH.—Sir Henry Alexander Miers, D.Sc., F.R.S., Vice-Chancellor of the University of Manchester, has been appointed by an Order of Council dated October 16, 1919, to be a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research.

LINSEED AND LINSEED OIL.—The Food Controller has issued an Order withdrawing linseed and linseed oil from the schedule of the Seeds, Oils, and Fats Order, dated June, 1919. The effect of this Order, which came into force on October 27, is that licences issued under the authority of the Food Controller will no longer be required to purchase or sell either linseed or linseed oil.

BUSINESS NOTICE.—Messrs. William and John Marvel, of Manchester, along with a few friends, have acquired a suitable works at Mossley, near Manchester, and have there commenced, under the name of the Mossley Color and Chemical Company Limited, the manufacture of all kinds of colours and pigments for the paint, paper, linoleum, and allied trades. The most up-to-date plant has been acquired. This country before the war was mostly dependent for these colours and pigments on supplies from Germany.

NEW INSULATING MATERIAL.—A new product suitable for use in electrical insulation is being obtained from the treatment of kelp in Australia, says *Engineering*. The moist precipitate is subjected to pressure and formed under pressure, after which it is hardened by treatment with formalin. The finished article is made by turning on the lathe, a process which is said to be perfectly successful, and a high polish is applied. The raw product is to be found in large quantities round the coast of Australia, and in particular on the Tasmanian shores.

FIRE.—From an unknown cause, there was a serious outbreak of fire on Wednesday, October 22, on the premises of Messrs. W. J. Bush and Co., Ltd., Manufacturing chemists, of Ash Grove, Hackney. The official description is as follows: "A brick building of one floor, about 60ft. by 20ft., used as a distilling-room, and the contents, damaged by fire, heat, smoke, water, and breakage. Richard Hampshire, aged 29; Walter Whaymand, aged 31 years; John Henry Hull, aged 27 years; and Thos. Wm. Arnold, aged 21 years, all severely burned and taken to hospital."

JAPANESE PATENT LAW.—According to a report published in the *Osaka Asahi*, the Japanese Government have established a committee for the revision of the patent laws under the chairmanship of Mr. Inuzuka, the Vice-Minister of the Department of Agriculture and Commerce. Three business men will have seats on this committee, which is to meet shortly at the Department of Agriculture and Commerce in order to prepare a Bill for the next session of the Diet. The four existing patent laws—i.e., patent law, designs law, utility models law, and trademark law—will be revised separately.

SOCIETY OF DYERS AND COLOURISTS.—At a meeting of the Manchester Section of the Society of Dyers and Colourists on Friday of last week, an illuminated address was presented to Mr. W. H. Pennington in appreciation "of the very valuable services rendered as chairman of the Section during the past 23 years." Mr. Pennington, in the course of a short review of his fifty years' association with the dyeing industry, said that the industry owed much to the foremen dyers of half a century ago, who, with their curious methods and mixtures, found glimmerings of scientific truth which they did not understand, although by their efforts and labours they laid the foundations of the scientific basis of the dyer's craft.

ARTIFICIAL COAL FROM SULPHITE-LYE.—At the Greaaaker cellulose mill, near Fredrikstad, Norway, a new method for producing fuel from sulphite-lye has recently been tried, and the result is exceedingly satisfactory. It will in this way be possible to extract surprisingly large quantities of fuel from this lye, which before was thrown into the sea. The mill will in this way obtain much more fuel than it needs for its own wants. For Norway, Sweden, and Finland, the new invention will be of considerable importance, as in this way a large part of the coal fuel which otherwise has to be imported, may be replaced with this artificial fuel. The factory is so far only built up to one-half of its intended size, but will soon be extended. The fuel is produced as a brownish powder, which is burnt in a special kind of oven. The factory and its new method have been the subject of much attention among specialists, and there is an influx of foreign engineers to look at it. The mill mentioned above will, besides fuel for its own use, have considerable quantities for sale.—*Paper Maker*.

CHEMICAL ENGINEERING CLASSES AT BIRMINGHAM.—Chemical engineering classes have been arranged for the winter session at the Birmingham Municipal Technical School. These classes last year were very successful, and the new course will consist of 30 lectures, for which Mr. W. A. Twine, A.M.I.M.E., A.I.C., chemical plant superintendent, Birmingham Corporation Gas Works, will be responsible. He has had a wide experience in chemical engineering and technology; and he makes full use of lantern and blackboard in showing chemical plant and processes. The syllabus is varied and comprehensive.

ZINC AND ZINC DUST PRICES.—Supplies of zinc dust are again very short, and the price of Australian high-grade (88-92 per cent. metallic zinc) has advanced to £75. per ton. A fair amount of atomised zinc dust—i.e., manufactured from virgin spelter—is now being made in this country. Some consumers find this atomised material satisfactory for their purposes, and it is generally obtainable at a few pounds below the price of the Australian "fume" dust. This atomised dust is only saleable when it exceeds 95 per cent. purity. Australian electrolytic zinc (99.95 per cent. purity) is unchanged at £42. per ton f.o.b. Australia for direct shipment to New Zealand, India, South Africa, and the Far East.

"POWERITE" JOINTING.—One of the most important items in the engineer's spares-box is a plentiful supply of gaskets for all joints. Moreover, the gaskets must be made of a reliable material, tested to resist high power, and withstand the action of steam, acid, oil, and alkalis. A dependable joint is a great boon to engineers, and to those to whom this important supply counts so much, the news that "Powerite" jointing is now available will be of great interest. Firms who are experiencing difficulty in obtaining jointing that will last without constant renewing are asked to communicate with the Powerite Steam Jointing Company, Ltd., 6-17, Devonshire Square, London, E.C. The proprietors have installed a large factory at Oakmoor, North Staffs.

CORNISH TIN MINING.—Mr. H. Rich, a director of Tinicroft Mines, Ltd., and Mr. William Thomas, the general manager of the Tinicroft mine, gave evidence on Thursday of last week before the Committee appointed by the Board of Trade to inquire into the non-ferrous mining industry. In their opinion, an amalgamation of the mines in the Central District would be advantageous. Mr. Rich said the Government should make a grant of £1,000,000. for this purpose, and he instanced the advance made by the Government to the Anglo-Persian Oil Company as a precedent. He thought that in view of the services rendered to the country by the Cornish tin-mining industry in the time of national emergency, the sympathy of the Government should assume practical shape in the manner indicated. Mr. W. Thomas gave technical evidence as to the position and prospects of the lodes in this area, and generally concurred with Mr. Rich.

TAR OILS IN GERMANY.—According to Professor H. Grossmann, of Berlin, says the *Technical Review* (quoting from the *Schweizerische-Chemiker Zeitung*) successful attempts have been made during the war to render Germany independent of foreign sources of substances hitherto derived from imported petroleum oil. Large quantities of tar oil were obtained from coal; and it is computed that the annual production of 1,500,000 tons of gas and coke-oven tars should yield some 15,000 tons of such tar oils. The production of tar by the low-temperature distillation of coal and lignites was also undertaken; but no accurate returns as to the quantity produced are yet available. Two principal methods of procedure are employed for obtaining the low-temperature tars. In the one, the distillation of coal is effected at a temperature not exceeding 500° C.: much tar, and little gas and ammonia being obtained. In the other method, which has hitherto been most generally employed, the coal is distilled in generators of various forms; the low-temperature distillates being removed without further subjection to a higher temperature than that of their production. In working-up these tars, large quantities of phenolic substances are obtained; and the utilisation in peace time of these products and of the coke produced is a pressing problem. Possibly Germany may be made entirely independent of imported tar oils by the use of the Bergin process, which renders possible the working-up of tar and tar products, including pitch, into very valuable materials, by subjecting them to the action of hydrogen. It may also be found possible to submit the raw coal or lignite to the action of hydrogen in such a manner that oil and benzene are obtained directly. The solution of this problem will put Germany on an entirely new footing as regards its supplies of combustible material and of power.

THE NEUHAUSEN ALUMINIUM INDUSTRY COMPANY.—Now that the war is over, and Germany is definitely defeated—only under these circumstances, it is well to emphasise,—the German directors forming part of the board of the Aluminium Industrie A.G., of Neuhausen, have retired from the directorate as from October 1, 1919. The withdrawal of these individuals is said to have been prompted by the desire to facilitate the reacquisition of the company's property in France. It will be remembered that the company is financially interested in the Société Française pour l'Industrie de l'Aluminium and the Société Anonyme des Bauxites de Frouée, of Marseilles, the latter producing crude bauxite and the former turning out calcined alumina. Shortly after the beginning of the war both companies were placed under French sequestration, on the ground, as was alleged, of German participation in the Aluminium Industrie A.G. and the presence of German directors on the board. The sequestration still continues at the present time, but negotiations are proceeding with a view to its removal. We know nothing of the real circumstances which dictated the action of the French authorities five years ago, but it is obvious that if the German directors had desired to assist the Neuhausen company in the respect mentioned they would have retired long ago, and not waited until the present time before handing in their resignations, which, after all, may be merely a nominal withdrawal. A catalogue of permitting of a resumption of the former state of affairs when conditions are favourable for the purpose. At the same time, the cause of the Neuhausen company will not have been advanced by the violent attack, evidently made on behalf of the German directors and the German interests in the company, which has just been made by a Frankfort newspaper on the French authorities and the French aluminium industry in connection with the maintenance of the sequestration.—*Elec. Rev.*

OUR BOOKSHELF.

PERFUMES AND COSMETICS. 4th edition. By George William Askinson, Dr. Chem. London: Hodder and Stoughton; 25s. net.

A very reliable book, which will be of material utility to those of our readers who are interested in the preparation of perfumery and cosmetics. "The Aromatic Vegetable Substances," "Chemical Products Employed," and "Operations Involved" are dealt with in lengthy sections. "The Yield of Essential Oils" is a tabulation of considerable importance. Various tables are included which are essential to good results.

KELLY'S DIRECTORY OF THE CHEMICAL INDUSTRIES, 1919. London: Kelly's Directories, Ltd.; £1. 5s.

This book was previously published under the title, "Directory of Chemists and Druggists, Including Manufacturing Chemists Etc." In the main it deals with the wholesale and retail chemists and druggists, etc., of Great Britain and Ireland, and as a compilation of such it is extremely useful. An effort has been made, however, to include the chemical industry, this accounting for the new title. Whilst the information contained about the chemical industry will be of service to retailers generally who require to approach chemical manufacturers from time to time, and *vice versa*, we fear that the new title may mislead many who require a purely industrial or industrial-commercial chemical directory. Pharmacy and pure or applied chemistry should never be incorporated in the same volume under the title used. The old title could not have been improved upon.

THE CONDENSED CHEMICAL DICTIONARY. Compiled by the editorial staff of the Chemical Engineering Catalogue. Publishers: the Chemical Catalogue Company, Inc.; \$5.

In this instance American energy supplies us with a book for which various individuals and firms have frequently searched in vain. The list of chemical items enumerated is very complete, covering both organic and inorganic products. It is obvious that to compress such a list into a volume of 500 pages makes brevity imperative; nevertheless, after taking this into account, it will be found that a very useful amount of working data, descriptive of every item, appears. In the case of synonyms, cross-references are used throughout.

LEGAL INTELLIGENCE.

Contract for the Sale of Permanganate of Potash: Arbitrators' Award.

A case arising out of a contract for the sale of permanganate of potash came before Mr. Justice Roche in the Commercial Court of the King's Bench Division on Tuesday. The plaintiffs, Messrs. Roth Schmidt and Co., of Great St. Helens, London, claimed from Messrs. D. Nagase and Co. Ltd., of Fen Court, London, the sum of £2,086. 8s. 2d., which plaintiffs said was payable to them by defendants pursuant to an award of Messrs. Alexander Pickering and Charles Mangold dated April, 1919.

Matters in dispute between the parties, in relation to a contract of September, 1918, for the sale of about 10,000lb. of permanganate of potash, were referred to the arbitrament and award of Messrs. Pickering and Mangold, and it was further agreed between them, said plaintiffs, that the costs of the reference and award should be in the discretion of the arbitrators. The arbitrators, having heard the parties, awarded that the permanganate of potash delivered by the defendants to the plaintiffs was not in accordance with the contract and that defendants should repay the sum they received from the plaintiffs with interest at the rate of 5 per cent. per annum, together with wharf charges and arbitrators' fees.

Defendants said the alleged award was bad on the face of it, in that it purported to award that defendants should repay the whole of the money received by them in respect of the goods, but did not award that plaintiffs were entitled to reject or return the goods. The award was also bad in that it awarded interest from the date of payment, for which there was no provision in the contract. Further, the award was bad for excess of jurisdiction. The contract was subject to the rules of the London Produce Brokers' Association, but the award was not in accordance with such rules, and the arbitrators, said defendants, had no jurisdiction to award the repayment of the purchase price.

Mr. D. C. Leck, K.C., opened the case for the plaintiffs, and said the claim was for the amount due under an award made on a contract for the sale to the plaintiffs of a quantity of permanganate of potash. Dealing with the points of defence, counsel said he did not know that they were likely to be insisted upon. He ventured to think that many of them were not really points of substance. The contract was subject to the rules and conditions of the General Produce Brokers' Association of London. The difficulty that arose at the hearing by the arbitrators was that the two arbitrators who were appointed by the parties were both members of the association, but neither of the contracting parties was a member of the association, and the committee of the association did not hear appeals except in cases where the parties to the contract were members of the association.

Mr. R. Goddard, for the defendants, submitted that the award was bad, and could not be enforced.

The hearing was adjourned.

On Wednesday Mr. Justice Roche gave judgment. His Lordship said one of the points of defence depended upon the procedure adopted at the arbitration. Defendants said there was an agreement that they should have the right to appeal from the award, and accordingly the award was not a final award which could be sued upon. A discussion took place as to whether the arbitration should be under the special rules of procedure of the General Produce Brokers' Association of London or whether it should be what was known as an open arbitration—that was to say, an arbitration conducted by the ordinary rules of law,—and he was satisfied on the evidence that the discussion really resulted in an agreement that it should be conducted in accordance with the ordinary rules of law. Therefore that defence failed. The next defence was that the award was bad, in that it purported to award the repayment of money, but did not award that plaintiffs were to return the goods. In his judgment, it necessarily followed by way of implication that the goods were to be returned, and that objection failed. The next objection raised was that the award was bad in that it awarded interest to run after the date of the award, and he held that in that respect the award was beyond his jurisdiction, and a small part of the plaintiffs' claim, amounting to £17. 19s. 6d., the plaintiffs could not recover. Dealing with the rest of the defence, his Lordship said he had to consider the point as to whether the contract was subject to the rules of the General Produce Brokers' Association of London. On the face of the written contract

it was said that the contract was to be so subject. He was not satisfied that there was any bargain between the parties that in doing away with the procedure of the General Produce Brokers' Association in regard to arbitration they were to do away with any of the substantive provisions of the produce brokers' rules governing the contract. Nevertheless, the defendants' contention, in his judgment, failed. They had entirely failed to satisfy him that the remedy granted by the rules was exclusive of all other remedies. He found in favour of the plaintiffs, and gave judgment for £2,055. 16s. 8d.

Sequel to a Soap Dispute.

At the London Bankruptcy Court on Tuesday an application was made for the discharge of Pieter Wachter, produce merchant, 47, Mark Lane, London, E.C. 3., and lately residing at 10, Hillsborough Road, East Dulwich, S.E. The Official Receiver reported that the Receiving Order was made on October 27, 1917, on a creditor's petition. Liabilities to rank for dividend were estimated at £254, and the assets were estimated to produce 9s. 2d.

The bankrupt was of Dutch origin and nationality, and about March, 1914, having been a produce merchant at Rotterdam, he came to this country as agent for a Dutch firm and took an office at 5, Duke Street, Tooley Street, S.E., with a capital of about £500. Owing to the war his principals failed, and at the end of July, 1914, he was called up for service in the Dutch Army, in which he held the rank of sergeant. In October, 1914, he obtained leave to come over here and see his wife, but never returned to Holland, so that he was now a deserter from the Dutch Army and unable to return to his own country. By the end of October, 1914, the whole of his capital had been lost on speculations for differences in various goods. He paid those losses, and then commenced business as a produce merchant. His business consisted of the importation of soap, desiccated coconut, and milk powders. He attributed his failure mainly to the adverse result of an action brought by him against Messrs. Grant, Hughes and Co. for damages for the non-delivery of 20 tons of white curd soap. The action was tried on March 5, 1918, and judgment went against him, with the result that the bankruptcy proceedings followed. The Official Receiver reported that the bankrupt's assets were not equal to 10s. in the £. on the amount of his unsecured liabilities; that he had omitted to keep proper books of account, and that he had contributed to his bankruptcy by rash and hazardous speculations.

Eventually the learned Registrar suspended the discharge for two years.

H. R. Merton and Co.'s Action for Slander.

In the King's Bench Division on Friday, October 24, before the Lord Chief Justice, an application to postpone the trial of the slander action brought by H. R. Merton and Co., Ltd., metal brokers, London, against Mr. Hughes, Prime Minister of Australia, was made on behalf of the defendant.

Mr. Stuart Bevan, K.C., for defendant, said the action was for defamation of character and for slander. The statements complained of were made in the summer and autumn of 1918. The first writ was issued in August, 1918, and the second in October of that year. There was an order for discovery; but on June 30, despite the absence of any affidavit of documents, the unusual course was taken of giving notice of trial. On that date Mr. Hughes, who had been in this country on business connected with the Peace Conference, was about to leave for Australia to take up his public duties, and it might have been under these circumstances that the notice of trial was given. The defence to the action was justification. The statements complained of in substance were that the plaintiffs, who were metal brokers, were of German origin and had German associations. Twenty pages of printed particulars had been delivered going into the whole history of the firm and involving very large discovery. There was a second ground on which the application for postponement of the trial was made—namely, the absence of two witnesses. It was decided to get Mr. Hughes to this country for the trial.

Mr. Douglas Hogg, K.C., for the plaintiffs, said he was content that the trial should stand over for a reasonable time, but not that it should stand over indefinitely. This was not an action for slander because the firm was called of German origin. If that had been the slander there would have been no action. The slander the plaintiffs complained of was the statement that, after four years of war, they continued to be working in the interests of Germany and to be agents of the enemy in this country. That was a very serious imputation

to make upon people of very high standing in the City who had been directors.

The Lord Chief Justice said that between now and the beginning of next sittings it would be possible to ascertain from Mr. Hughes when he could come to this country if it was thought necessary for him to be at the trial. The case could be mentioned again at the beginning of next sittings.

Soap Merchant's Failure.

At the London Bankruptcy Court last week, the public examination was appointed to be held of Sarah Alice Duffield and Wynyard Hamilton Ryde Weller, temporary Government clerk, late of 102, Woodside Road, Wood Green, partners in the firm of Lindley Duffield and Co., lately carrying on business at 1, and 2 Great Winchester Street, E.C. Upon the case being called on for hearing the debtor Duffield did not appear, but the Official Receiver said he had received a medical certificate on her behalf stating she was suffering from a nervous breakdown, and he would therefore only be able to examine the debtor Weller.

The joint statement of affairs filed by the debtor Duffield disclosed gross liabilities expected to rank against the estate for dividend estimated at £8,508. 11s. 2d., and assets estimated to produce £50., thus showing a deficiency of £8,458. 11s. 2d.

Replying to questions put by the Official Receiver, Weller stated that after his previous failure in 1915, when his liabilities amounted to £697., he was in employment, and since August, 1918, had been in receipt of a salary of £550. a year in a Government department. On July 1, 1917, he entered into partnership with Sarah Alice Duffield, but he put no capital into the business and was to receive £3. a week for keeping the books and one-half share of the net profits. Finding he could not give the time to the partnership business, he on September 1, 1917, wrote to F. L. Duffield (the manager) tendering his resignation, but took no other steps to dissolve the partnership; thereafter he never attended at the firm's offices, and in his view he ceased to be a partner as from that date, when there were no debts outstanding. Debtor said he did not know anything about an action brought against the company for breach of warranty in connection with a sale of a large quantity of soap, in which the company were ordered to pay £2,840 damages and costs. Debtor was questioned with regard to about 33 tons of soap which was under the control of the company at the termination of the business, and he said he believed the manager, Mr. Duffield, had invoiced that soap to himself at £15. per ton, in lieu of salary. He further stated that he never saw the books of the partnership and had no idea of the extent of the liabilities until the estimate given by his partner was mentioned at the first meeting of creditors.

Eventually the learned registrar concluded the examination of Weller and adjourned the examination of Mrs. Duffield.

Customs Seizure of Pyrogalllic Acid: Chemical Importer's Action.

A motion on behalf of the Crown to stay the Chancery action by Mr. John Brown, trading as Brown and Forth, chemical dealers and importers, of Farringdon Road, E.C., and Dolefield, Bridge Street, Manchester, came before Mr. Justice Sargent in the Chancery Division on Wednesday. The matter had been before the judge in the Vacation Court on a motion for an injunction by the plaintiff to restrain Mr. W. Buckley, Customs and Excise officer at Manchester, from dealing with 5 tons of pyrogalllic acid which he had seized under a Proclamation prohibiting the importation of certain goods under the section of the Customs Regulations Consolidation Act, 1876, dealing with "arms, ammunition, gunpowder, and other goods."

Mr. Giveen, for the Crown, asked for the action to be stayed pending the hearing of the proceedings instituted by the Crown on the revenue side of the King's Bench Division. He said the matter affected very widely the rights and privileges of the Crown. There was in it a substratum of detainee, and the King's Bench Division should be the venue of the trial. In his statement of claim the respondent said that the seizure was invalid and not justified under the Proclamation, and he demanded the delivery of the goods. In the defence it was said that the goods were imported on or about August 19 without any licence, and the defendant

seized them under the Proclamation. An information was filed on the Revenue side of the King's Bench Division, and was delivered on October 22.

Mr. R. A. Wright, K.C., for the respondent, said that since August 29 attempts had been made to have the matter brought to adjudication. The question was very simple, turning merely on the meaning of a particular clause in the Customs Consolidation Act. The plaintiff was a businessman whose operations had been interfered with, and he was not the only businessman in that position. A large part of the mercantile community was being interfered with by administrative acts which, so far as could be seen, were absolutely without justification. He submitted that his lordship had discretion to ensure that there was a speedy trial of the action.

In the end it was agreed that an early day should be fixed for the trial of the action, subject to the convenience of the Attorney-General.

Burnt By Acid: Workman's Compensation Claim.

In the Bow County Court, last week, before Judge Graham, K.C., sitting with Dr. Bate, as medical referee, application was made under the Workmen's Compensation Act, by Henry George David Turner, for an award against Messrs. Abram Lyle and Sons, sugar refiners, of Silvertown.

According to the applicant, on July 4, he was charging iron pipes with char, a kind of bone substance with acid in it, when there was an explosion, and some hot acid and char splashed into his face. He was badly burned on the face and neck, and some of the acid and char went into his eyes. The process was to charge the iron pipes, which were surrounded with furnaces, with this char in a wet form, and it came out dry two floors below. It was used in the process of sugar refining. Applicant said he was paid 25s. a week to July 30, when it was stopped, but he had not been able to work since, whilst his right eye was so bad that everything was a blur.

Dr. Crowley agreed that the lad was not fit to go back to work.

For the defence, Dr. Toogood said he did not believe a word the lad said about his sight; in fact, he had no hesitation in saying it was a lie. The lad was fit to go back to work amongst chemicals in July, and was more fit now. He did not consider that acid on the eyelid would hurt the eye, as the eyelid was there to protect the eye.

Dr. Bate examined the lad, and after a consultation with his Honour Judge Graham decided that he could have worked at the end of July, and found for the respondents, with costs.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 4, Queen Anne's Gate Buildings, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

British West Indies.

A firm of importers in Trinidad are desirous of representing United Kingdom firms as buying agents for cheap paraffin candles, on a commission basis. (Reference No. 883.)

A firm of importers in Trinidad are desirous of representing United Kingdom firms as buying agents for carbonic-acid gas, on a commission basis. (Reference No. 884.)

A firm of importers in Trinidad are desirous of representing United Kingdom firms as buying agents for manures and fertilisers, on a commission basis. (Reference No. 888.)

Italy.

An Italian desires agencies (preferably exclusive for Italy) for British firms dealing in toilet soaps. (Reference No. 896.)

Switzerland.

An agent at Zurich wishes to secure the representation in Switzerland of United Kingdom firms dealing in toilet soap. (Reference No. 902.)

Brazil.

A well-established firm of commission agents in Rio de Janeiro interested in chemicals are desirous of representing British firms in Brazil, and ask for catalogues, samples, prices, etc. (Reference No. 906a.)

THE FUTURE OF THE GAS INDUSTRY.

THE NEED OF THE CHEMIST.

MR. C. CARRINGTON BARBER, the new president of the Midland Junior Gas Association, delivered his presidential address at the opening meeting of the session, which was held at the Council House, Birmingham, on Saturday last.

The question of the conservation of fuel was, he said, of utmost importance. The price had risen considerably, and it behoved all gas engineers to make the fullest use of any class of fuel. Coke dust was for a long time a drug on the market, but a demand had been created for its use by burning it on boilers, the grates being suitably equipped. On the works upon which he was engaged, there had been installed two Babcock and Wilcox boilers, fitted with chain grates for that purpose, and they were working exceedingly well. By their use they were able to burn the whole of the dust made on the works in that manner.

The quality of gas coal had to be considered in respect to the ash content, not only because of its effect on the yield of gas per ton of coal carbonised, and the yield of tar and ammonia, but also because of its effect on the quality of the coke produced. When times became more normal and there was not the excuse of shortage of labour at the collieries, preventing the proper screening and picking of the coal, it would be the duty of gas engineers to insist upon a reasonable ash content. He had known cases in the past two or three years where the ash had been as high as 30 per cent., and generally over 20 per cent. It meant that for every 100 tons of coal carried by the railway companies, between 20 and 30 tons was inert material. Surely it would be the duty of the Government to see that every effort was made to ensure that all coal was properly screened, and thus make available wagons for more useful work.

The process of gas manufacture was a chemical process, and as such the gas engineer should have a sound chemical and physical knowledge in addition to being an engineer. Where the works were sufficiently large a chemist should always be employed. He considered that every works making over one hundred million feet of gas per annum came under that heading. The importance of that could not be emphasised too much, since in the majority of cases he would more than save his salary in a short time. When visiting different gas works, it had been astonishing to him to find in many cases that the engineer had been unable to tell him the quantity of ammonia passing the ammonia washers, or the amount of tar entering the purifiers. Those were details, but it was to a very great extent details that mattered, and much money could be saved if those and other matters which were often considered trivial were given closer attention. It was to their lot as juniors that much of that work devolved, and that was his reason for dwelling on the subject. The whole of the apparatus on the works dealing with the extraction of tar, ammonia, sulphur, etc., should be in the charge of the chemist.

BY-PRODUCT COKING.

AT the opening meeting of the session of the Staffordshire Iron and Steel Institute at Dudley on Saturday, Mr. W. Macfarlane said that during the war period over 1,750 by-product coke-ovens were laid down at a cost of nearly £5,000,000., to which the Ministry of

Munitions contributed £1,250,000. It was anticipated that the total output of coke from these ovens would be about 16½ million tons per annum when the plants were in full operation, approximately a 50 per cent. increase upon the pre-war output. This increase in the production of coke would require 8½ million tons additional coal per annum, representing the labour of 33,000 coal-miners. As far as practicable, all bituminous coals should be subjected to a coking, or semi-coking, process at a comparatively low temperature, so that by-products should not be wasted. If only half of the coal used in Great Britain for manufacturing and domestic purposes were semi-coked there would be a yield of two hundred million gallons of motor-spirit, which was double our pre-war output; two million tons of pitch, half a million tons of ammonium sulphate, and 40 million tons of semi-coke.

If the major portion of the 36 million tons of coal consumed in our homes were previously treated for residuals, even if only partially, there would be a national enrichment, and the air of our cities would be more pure, and sunlight more abundant and active. Alcohol might, for some purposes, be substituted for coal, and would help us a little way towards conserving our reserves. As a substitute for petrol, alcohol had a rival in coal-tar benzene, a product which was certain to be turned out in the future in far larger quantities than was formerly the case. More economic burning of coal would lead to the recovery of more coal-tar products, of which benzene was one of the most important and plentiful. Many experiments had been made on mixtures of alcohol and benzene as a fuel for motors. A mixture of alcohol with 10 per cent. of benzene furnished a cheap motor fuel, costing not more than 6d. per gallon, and utilisable in existing petrol motors with little or no alteration in the carburettor.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

(SPECIALLY CONTRIBUTED.)

There is no immediate prospect of a return to the production which the Cumberland by-product coke-ovens were securing five weeks ago. In the absence of a settlement of the iron-moulders' strike the hematite pig-iron trade necessarily remains dull, the local foundries themselves requiring quite 1,000 tons less of ordinary iron than was the case at the beginning of September, and the slackened activity in the steel-rail trade also accounts for a diminution in the make of a quality of iron for which local coke is almost exclusively used. The outlook, therefore, remains poor, and it is difficult indeed to believe that the re-lighting of additional furnaces will now be possible this year. In that event, of course, the by-product coking industry will continue to be hard hit. No more than two of the plants are in full operation, the majority at present working only at one-third of their capacity, and it is doubtful whether output can be maintained even at this low level. It is curious that despite the fall in the North-west Coast smelters' make of iron the absorption of East Coast coke is unchanged, the supplies this week to the Furness district totalling 13,500 tons, and to West Cumberland nearly 8,000 tons. The output of by-products has, of course, fallen off considerably. Much more benzole is required than can be made, and a similar state of affairs exists as regards sulphate of ammonia, which is going wholly to home consumers. Pitch is in livelier request and stocks have decreased, and creosote is also fairly strong.

RELAXATION OF EXPORT PROHIBITIONS.—The Board of Trade announce that the following goods, which have hitherto been included in List A of prohibited exports and have thus been prohibited to all destinations, have now been removed from it: Cotton-seed oil; oleo; sesame oil; lard, imitation (compound); and lard, neutral.

FERTILISER NEWS.

(SPECIALLY CONTRIBUTED.)

Nitrate of Soda.—Under existing conditions, with only one seller at fixed prices, a market can hardly be said to exist in Chili; but the industry is gradually returning towards a normal state, and a sufficient supply of tonnage is alone required to set things straight by the removal of the enormous stocks accumulated since the armistice. These, as already stated in these columns, reached on October 1 no less than 1,712,000 tons, or more than double the quantity carried at the corresponding date in the years before the war, and representing, at an average of 4,000 tons each, over 400 cargoes. There is, of course, no immediate prospect of such an amount of shipping being available, and extremely high freights have consequently had to be paid to tempt neutral vessels to the long voyage from the West Coast, while those of the Allies have been engaged in other directions. Fortunately, however, there are at last signs of an increasing supply, and the shipments of the Chilean fertiliser to Europe and the United States will no longer be on the negligible scale of the past nine months. Many of the fine French sailing ships which formerly ran like clockwork with coals from the Tyne to Iquique, and thence with nitrate to Dunkirk, Nantes, and Bordeaux, were sunk by German submarines, but the survivors are returning to the trade, the *Rhone* sailing last month from Chili; while up to 250s. per ton was recently paid for a big steamer to the Continent, 160s. has just been accepted by another for early 1920 despatch to the United Kingdom; and freights will, as we all along anticipated, eventually come down to a much lower level. So much for the nitrate outlook in Chili, the improvement in which is undeniable. That in Europe, by no means as clear, will be examined in due course.

Dutch Fertiliser Notes.—With respects to results of boring for potash at Ratum and Plantengaarde, in Holland, the Agricultural Minister proposes an allocation of 65,000 florins for a closer investigation of the strata for potash salts. One authority, however, maintains that reports hitherto received have been too optimistic; but, on the other hand, there is no reason to abandon the search. The results, it appears, show a considerable geological similarity with the developments in the Weser and Zanten borings.

A recent report on the Dutch fertiliser industry states that it has had to suffer considerably from the importation of Chilean saltpetre, the quantities of which have far exceeded the requirements of the country. Financial considerations also are the subject of much complaint owing to the activity of the Dutch Overseas Trust Company and the Dutch Export Company.

A syndicate has obtained the concession of the Asahan (Dutch East Indies) waterfall, and intends to take 10,000 H.P. from it, and constructional work will soon begin. It is principally intended for fertiliser production. The chief engineer for water power and electricity, Heer Roelofsen, is to be absent five months in America to collect information on nitrogen production, etc.

Sulphate of Ammonia.—There is a firm market for all fertilisers, but deliveries appear to be delayed pretty generally. There are still suggestions that the price of sulphate of ammonia to home users is regarded as sufficiently high to check business to an extent; but, in view of the number of orders coming in, it is difficult to see how this view can be justified. Against this, moreover, some profitable sales for export are said to have taken place at £24. per ton cash. It appears, therefore, that Continental farmers are able to afford to pay this figure plus freight, or something fully equal to £25. per ton for their fertiliser.

Basic Slag.—The delayed deliveries which mark most divisions of the fertiliser market at the present time are especially acute in basic slag. This is a matter that recurs every year, and so far appears to have defied all attempts to rectify it. It does not appear that farmers have been more than usually backward in placing their orders; the reason probably lies elsewhere, and the condition has no doubt been complicated very considerably by the recent railway strike.

Superphosphates.—Many manufacturers of superphosphate declare that they need a freer supply of rock phosphate, as we are said to be over 100,000 tons behind the war standard of 1918. During September the imports of rock phosphate into this country were 22,423 tons, as against 29,000 tons in September, 1918, and 36,500 tons in the previous September. So far during the first nine months of this year we have only imported 260,000 tons of phosphate of lime and rock phos-

phate, which is a drop of over 100,000 tons in comparison with the figures for the corresponding nine months of last year. There seems to be something like a world shortage of phosphate, of which this and other things are outward and visible signs. Take, for example, the recent report of a serious shortage of phosphatic fertilisers which is declared to have already prevailed in South Africa for nearly three years owing to lessened imports. Steps are being taken there to utilise more fully the Saldanha Bay phosphate deposit.

Bone Meals, etc.—Bone meals, raw and boiled, are busily inquired for, and prices seem to be above the closing values of the past season. At the same time, definite general quotations are not easy to get. Pure steamed bone meal, 1 per cent. ammonia and 60 per cent. phosphate, in bags, quotes £13. 10s. to £14. per ton, ex works; whilst pure dissolved bones, 3 per cent. ammonia and 32 per cent. phosphate, register £15. 10s. to £16. per ton. There is a fair inquiry for meat meal with values based on 30s. per unit of ammonia. There is not a great deal offering in tankage, and the nominal value is still round about 30s. for ammonia and 2s. for phosphate. In dried blood there is little doing, as the offerings are but small. The figures are as above.

Other Fertilisers.—Potash manures are still in small supply, but there are signs of improvement. In all other fertiliser descriptions very little trade appears to be passing, and the position seems to have been stereotyped for the time being in high prices and short supplies.

Alsation Potash.—The imports of Alsation potash salts during the week ended October 25 were 575 tons sylvinite, 14 per cent. (French kainit), and 389 tons of sylvinite, 20 per cent. (French potash salts). Current quotations are as follows: Sylvinite, 14 per cent., £7. per ton; sylvinite, 20 per cent., £8. 7s. 6d. per ton; and muriate of potash, 80 per cent., £19. 7s. 6d. per ton.

SOUTH WALES NOTES.

(SPECIALLY CONTRIBUTED.)

There are now nearly 400 mills operating, and still the outputs are not sufficient to supply the needs of foreign markets. Export business is very good, and there is now less difficulty in shipping arrangements. The Far Eastern markets are particularly strong just now, and it is likely that further mills will be set going shortly. The total shipments from Swansea for the week totalled 68,497 boxes, as against 104,838 boxes in the previous week. The receipts from the works were 8,000 boxes, thus leaving stocks in dock warehouses and vans at 166,949 boxes, compared with 152,107 boxes at the same date last year.

Patent-fuel prices are somewhat stationary, and, owing to the volume of business in hand, not many fresh orders are being entertained, there being sufficient demand for the next two months' production. Several large cargoes have been shipped this week.

The markets for coke are much stronger, and as much as £5 10s. per ton has been obtained for export business, which is chiefly directed to St. Malo, Buenos Ayres, Rouen, Treport, and Valencia. All the ovens are working well. The strike at Ebbw Vale has been settled, the manager, Mr. Fred Mills, having made a satisfactory offer, and in consequence of this Mr. Mills is to be asked to resign the chairmanship of the South Wales and Monmouthshire Iron and Steel Makers' Association. The Ebbw Vale men resumed work on Wednesday morning. Similar offers—which, it is thought, will be accepted—are to be made to the Tredegar and Dowlais men.

Sulphate of ammonia outputs have suffered during the continuance of this dispute, as some of the coke ovens had to be shut down for short periods. Sulphate of ammonia is passing very freely, and there are little or no stocks on hand. Fresh outlets for this fertiliser are presenting themselves, and with the anticipated increase in the number of ovens which will be working at the commencement of next year the yields will be steadily consumed. Export business is slightly increasing, but the home requirements at present will not allow much expansion of foreign business.

ANGLO-CHILIAN NITRATE AND RAILWAY COMPANY, LTD.—No interim dividend will be paid on the preference or ordinary shares.

NEW COMPANIES.

Anglo-United Oilfields, Ltd.—Capital £225,000., £1. shares. Office: 8, Princes Street, E.C. 2.

Centrifugal Separators, Ltd.—Capital £275,000., in 175,000 A. and 100,000 B. shares of £1. each. Objects: To take over the business carried on by the Hydraulic Separating and Grading Company, Ltd., and the patents and other assets thereof. Solicitors: Nicholson, Graham and Jones, 24, Coleman Street, E.C.

Electro-Metallurgical Extraction, Ltd.—Capital £30,000., £1. shares. Objects: To manufacture, recover, distil, refine, sell, and deal in all manner of chemical elements, products, by-products and residuals, etc. Solicitors: Herbert Smith and Co., 62, London Wall, E.C.

Trinidad Western Oilfields, Ltd.—Capital £150,000., 5s. shares. Registered office: 448, Strand, W. 2.

A. Stedman and Sons, Ltd.—Private company. Capital £25,000., £1. shares (10,000 ordinary, 10,000 non-cumulative 7 per cent. part preference, and 5,000 6 per cent. cumulative preference). Object: To take over the business of oil refiners, colour, paint, and varnish manufacturers and wholesale drysalers carried on at the Grove Works, Hatcham Road, Old Kent Road, S.E. Solicitor: W. H. Cahill, 22, Basinghall Street, E.C.

Callard, Ltd.—Private company. Capital £5,000., £1. shares (1,000 10 per cent. cumulative preference). Oil refiners, electro-platers, smiths, chemists, engineers, etc. Solicitor: H. S. Holt, 6, Gray's Inn Square, W.C. 1.

Calvery Dyes, Ltd.—Private company. Capital £25,000., £1. shares. Object: To carry on at Mirfield, Yorks, and elsewhere, the business of manufacturers of and dealers in aniline, and other dyes, etc. Solicitors: Clough and Crabtree, Cleckheaton.

E. R. Watts and Son, Ltd.—Private company. Capital £20,000., £1. shares. Scientific instrument makers, etc. Solicitors: Bolton, Jobson and Yate Lee, 2, Temple Gardens, E.C.

Four Ashes Manufacturing Company, Ltd.—Private company. Capital £100,000., £1. shares. Manufacturing chemists and manufacturers and distillers of tar and all products and derivatives therefrom, etc. Solicitor: W. O. Vizard, 10A, Featherstone Buildings, W.C. 1.

Frome Vinegar Brewery Company, Ltd.—Private company. Capital £12,000., £1. shares (6,000 A., 3,000 B., and 3,000 C.). Registered office: The Vinegar Brewery, Frome.

Heaths (London), Ltd.—Private company. Capital £5,000., £1. shares. Pharmaceutical, analytical, manufacturing, or consulting chemists, druggists, drysalers, oil and colourmen, etc. Solicitor: T. F. Gaskell, 71, Lord Street, Liverpool.

Lower Lansalton China Clay Company, Ltd.—Private company. Capital £100,000., £1. shares. Registered office: 17, Albion Street, Hanley.

Middridge Limestone Company, Ltd.—Private company. Capital £23,000., £1. shares (3,000 preference). Registered office: Cargo Fleet Iron Works, Cargo Fleet Road, South Bank, Yorks.

New British International Oil Syndicate, Ltd.—Private company. Capital £26,250., in 25,000 ordinary shares of £1. each and 25,000 founders' shares of 1s. each. Registered office: 3, London Wall Buildings, E.C.

Niggerins, Ltd.—Private company. Capital £5,000., £1. shares. Object: To take over the business of the Anglo-Canadian Trading Company. Chemical and colour merchants and manufacturers, and brokers, exporters and importers, engineers, etc. Solicitor: E. H. Banks, 26, North John Street, Liverpool.

Russells (Manchester), Ltd.—Private company. Capital £20,000., £1. shares. Manufacturers of and dealers in asbestos and insulating material, dealers in engineers' stores, oil refiners, chemical and dye manufacturers, manufacturers of and dealers in rubber, etc. Registered office: Lands End Works, Rhodes, near Manchester.

Sacol Chemical Company, Ltd.—Private company. Capital £10,000., £1. shares (6,000 cumulative 10 per cent. preference). Registered office: Bankside, Sculcoates, Hull.

William Jarvie, Ltd.—Private company. Capital £2,000., £1. shares. Registered office: Eclipse Chemical Works, Whittington Street, Coatbridge.

Selsey Utilities Company, Ltd.—Private company. Capital £15,000., £1. shares. Manufacturers of and dealers in manure, manurial products, and chemical and other fertilisers, etc. Registered office: Phipps Estate Office, High Street, Selsey.

Sozon Oil Company, Ltd.—Private company. Capital £3,000., £1. shares. Manufacturers of "Sozon Oil" for leather belting, etc. Registered office: 152, Marsland Road, Brooklands, Cheshire.

Tembuland Coal, Iron and Chemical Company, Ltd.—Private company. Capital £100,000., in 210,000 cumulative preference shares of 2s. each and 79,000 ordinary shares of £1. each. Registered office: 25, Rood Lane, E.C. 3.

Tetney Oil and Meal Company, Ltd.—Private company. Capital £500., £1. shares. Manufacturers of and dealers in fish meal, fish guano, meal and glue, etc. Registered office: 2-4, Cheapside, E.C.

Voxol Products Company (1919), Ltd.—Private company. Capital £50,000., £1. shares. Objects: To take over (a) the business of a tallow, grease, and oil refiner and fertiliser manufacturer carried on at Vauxhall Road, Liverpool, by O. Toole; (b) the business of edible fat and oil refiners and merchants carried on at Vauxhall Road, Liverpool, by the Voxol Products Company, Ltd. Registered office: 8, North John Street, Liverpool.

Alexanders, Ltd.—Private company. Capital £10,000., £1. shares. General merchants, commission agents, produce brokers, drysalers, oil and colourmen, importers, exporters, and manufacturers of and dealers in chemicals and their compounds, oils, paints, starches, etc. Registered office: 166, Buchanan Street, Glasgow.

John Scott and Watson, Ltd.—Private company. Capital £3,000., £1. shares. Object: To acquire the business carried on at 78, Berkeley Street, Glasgow, as the "Kildust Company," and the business carried on at the Phoenix Chemical Works as "Scott and McQueen," and to carry on the business of manufacturers of labour-saving preparations, etc. Registered office: Phoenix Chemical Works, 61, Pollok Street, Pollokshaws, Glasgow.

Robert A. Munro and Co. (Ireland), Ltd.—Private company. Capital £10,000., £1. shares. Chemical produce and fertiliser merchants, etc. Registered office: 102, Grafton Street, Dublin.

North-West Canada Oil and Gas Syndicate, Ltd.—Private company. Capital £5,005., in 5,000 ordinary shares of £1. each and 100 founders' shares of 1s. each. Registered office: 13, Copthall Court, E.C.

Premier Perfumery Company, Ltd.—Private company. Capital £1,500., £1. shares. Object: To take over from B. A. Chapman, Joan H. Daniel, and R. D. Judd the business of manufacturers and distillers of perfumes carried on by them in London. Registered office: 61-2, Chancery Lane, W.C. 2.

Pemberton, Ansell and Co., Ltd.—Private company. Capital £5,000., £1. shares. General merchants, manufacturers' and merchants' agents, importers and dealers in chemicals, oils, grease, etc. Registered office: 92, Fleet Street, E.C.

Paragon Chemical Company, Ltd.—Private company. Capital £5,000., £1. shares. Dye and chemical manufacturers, dyers, bleachers, etc. Registered office: The Paragon Chemical Works, Baxenden, near Accrington.

BOOKS RECEIVED.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

October 20th to 25th (inclusive).

- Determining Carbon Contents of Steel, Ferrous and Non-ferrous Alloys. Batty, G. 25,942.
Removal of Fats, Oils, etc., from Casks, etc. Bell, T. M. 25,992.
Removal of Volatile Solvents from Material Treated Therewith. Bollmann, H. 25,729.
Paints, Stains, and Varnishes, etc. Burlin, A. L. 25,810.
Cement Paint. Burlin, A. L. 25,811.
Plaster of Paris. Burlin, A. L. 25,114.
Regenerative Coke-ovens. Coke and Gas Ovens, Ltd.; and Kimbell, H. F. 26,026.
Liquefying or Reducing Viscosity of Oil. Cross, A.; and Miller, W. H. 25,644.
Filters. De Haën Chemische Fabrik List, E. 26,045.
Manufacture of Articles of Paraffin Wax, etc. Elborne, W. 25,852.
Non-porous Waterproof and Acid-resisting Cement. Elborne, W. 25,853.
Rotating Colour Mixing or Blending Devices. Ewart, J. S. 25,877.
Distilling Bituminous Coal, Brown Coal, and Shale by Superheated Steam. Gercke, M. 25,655.
Compounds of Radium. Hedstrom H. O. 25,688.
Purification of Sulphur. Hood, J. J. 26,231.
Alkyl-substituted Alkyl Halides, and Condensation Products Therefrom. Imray, O. (Soc. of Chemical Industry in Basle). 25,806.
Azo Dyestuffs. Imray, O. (Soc. Chem. Industry in Basle). 25,916.
Treatment of Minerals or Products Containing Iron and Titanium and/or Vanadium. Kjellberg, B. P. F. 25,687.
Preparing Sulphates of Sodium and Magnesium. Low, A. M. 25,943.
Copper Alloys. MacGuckin, C. J. G. 26,136.
Clarifying Liquids Containing Finely Divided Matter in Suspension. Mackey, W. M. 25,721.
Extraction by Solvents. McMullen, W.; and Rickets, W. J. 26,112.
Synthesis of Nitric Acid. Mage, L. A.; and Nougier, L. A. 26,135.
Water-soluble and Water-emulsible Substances. Melamid, M. 25,932.
Sodium Sulphate. Salzwirk Heilbronn. 25,676.
Solutions of Acetyl Cellulose. Silberrad, O. 26,158.
Centrifugal Fluid-extractor. Storr, F. R. 25,837.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 6d. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Calcium Nitrate. C. T. Thorssell, and H. L. R. Lundén, Gothenburg, Sweden. British Patent, 131,493, of 1918.

Calcium nitrate is formed by bacterial oxidation of calcium cyanamide by trickling the solution over a bacteria bed formed, for example, by a layer of garden soil mixed with powdered coke. Calcium cyanamide is dissolved in water which may contain carbon dioxide to precipitate free lime, and sufficient of the solution is added to a solution of calcium nitrate to obtain complete oxidation of the cyanamide in one treatment. Part of the calcium nitrate is separated, and to the remainder cyanamide solution is added to obtain a solution of the same composition as that previously treated.

Ammonium Compounds. C. J. Montgomery, Saltcoats, Ayrshire; and E. R. Royston, Liverpool. British Patent, 131,609, of 1916.

Ammonium compounds are obtained from the nitrogen of the atmosphere by introducing into the cylinder of an internal-combustion engine, after the ignition of the combustible mixture, either a hydrocarbon oil or spirit or hydrogen, and providing in the cylinder or in the exhaust-pipe, or in both places, a catalyst which causes the formation of ammonia. The catalyst used in the cylinder is one which promotes the combination of nitrogen and hydrogen, such as an osmium catalyst; and that used in the exhaust-pipe is one which will cause reduction of nitrogen, such as nickel. The catalyst is prepared by soaking asbestos sheets in a solution of the metal, and after heating the sheets mounting them between perforated metal sheets in the head *e* of the cylinder, on the head *h* of the piston, and in the exhaust-pipe *j*. The engine is provided with an air-inlet valve *b*, an oil-inlet valve *c*, and a valve *d* through which water is injected immediately

after the ignition of the charge. The excess of hydrocarbon may be introduced into the cylinder by leaving the oil-inlet *c* open longer than usual. The exhaust gases are passed through a shower of sulphuric or other acid, and then bubbled through the partially neutralised acid solution to concentrate it, or the gases are cooled to separate water and ammonia.

Chlorides. W. Heap, Stockport; and E. Newbury, Manchester. British Patent, 131,039, of 1918.

Anhydrous chlorides are obtained by treating with a mixture of chlorine and producer gas free from hydrogen an oxide, hydrate, carbonate, or organic salt or hydrated chloride of the metal. An example describes the production of chlorides of the cerium earths. The mixed gases may be passed over a catalyst such as animal charcoal before reaching the metal compound. The volume of chloride is equal to that of the carbon monoxide in the producer gas, but, according to the Provisional Specification, the carbon monoxide may be in excess.

Nitric Acid and Nitrogen Peroxide. W. R. Bousfield, Hendon, Middlesex; and Nobel's Explosives Company, Glasgow. British Patent, 131,642, of 1918.

The absorption of nitrogen peroxide from gases such as those obtained by the oxidation of ammonia or by arc processes, is effected by strong nitric acid with sufficient cooling to absorb the heat liberated. Particulars are given as to the amount of cooling required. In dealing with the products of the oxidation of ammonia, the bulk of the water is preferably removed by a preliminary cooling before absorption in the nitric acid. The nitrogen peroxide is recovered by distillation, and the nitric acid, after concentration if necessary, is used again; or the solution may be oxidised by means of oxygen in the known manner to produce nitric acid; or liquid nitrogen peroxide may be added to produce the known separa-

tion into two layers, from one of which 90—100 per cent. acid is obtained. The apparatus employed, when nitric acid is to be produced, is a combination of four elements, each of which is known *per se*—namely, means for producing a gas mixture containing nitrogen peroxide, means for bringing the gas into contact with liquid nitric acid, means for cooling the nitric acid, and means for oxidising the solution.

Fermenting Wort. A. T. Henley, Cork. British Patent, 131,021, of 1918.

To prevent loss of alcohol in blowing air through fermenting wort, the air is either saturated with water-vapour at the temperature of fermentation before entering, or cooled to a sufficient degree on leaving the wort to condense any alcohol-vapour entrained by it. In the arrangement shown in Fig. 1, the air passes through a closed vessel *b* containing water kept at the required temperature by steam-pipes *c*, and thence passes through pipes *e*, *f*, *g* to the wort. In the form shown in Fig. 3, the air leaving the wort passes through a funnel-shaped outlet *h* with a hollow lining *j*, through which cooling liquid is circulated. The condensed alcohol-vapour runs back into the wort.

Hydrogen. E. K. Rideal and H. S. Taylor, London. British Patent, 131,328, of 1918.

In the manufacture of hydrogen by alternately passing steam over heated iron and reducing the iron oxide produced by carbon monoxide or by a mixture of carbon monoxide and carbon dioxide, the effluent gases from the reduction stage are converted into carbon monoxide for reuse therein by passing through a bed of incandescent coke, the temperature of which is maintained by the periodical blowing through of air or oxygen. The initial supply of carbon monoxide may be obtained by admitting steam to a producer, using the water gas produced in the preliminary reducing stages, and then passing the effluent gases through incandescent coke as described above.

Separating Liquid Mixtures. E. A. Cunningham, London. British Patent, 131,346, of 1918.

Continuous apparatus for separating mononitrotoluenes and other mixtures by fractional distillation and crystallisation consists of a packed distilling column A, A', Fig. 1, fitted with an internal heating coil B, B' together with crystallising tanks D in duplicate or divided into sections which are used alternately. The mononitrotoluene mixture is fed to the top of the lower section A' of the column by a pipe *c* supplied from alternately used feed tanks C. The vapours of the ortho and meta compounds generated in the section A' are separated in the section A, the ortho compound emerging by the vapour outlet E. The residual mixture of meta and para compounds is led by a pipe *d* from the base of the section A' to alternately used tanks D, and the para compound is crystallised out. The column A, A' is packed with metallic gauze or beads, and is provided with a steam or other jacket *a*. The supply of steam to the coil B, B' is regulated

by a valve *b*² in the supply pipe *b*¹ which is automatically controlled by a thermostat *b*³ at the top of the column. The relative temperatures of the sections A, A' can be controlled by adjusting the escape of steam from the ends of the steam coil. The bottom *d*³ of the crystallising tanks D, shown in plan in Fig. 2, is divided into segments, alternately perforated, and is covered with a segmental plate *d*⁴ connected to

a lever *d*⁵. After crystallisation has taken place, the plate *d*⁴ is rotated to uncover the perforated segments and to allow drainage to take place.

Vanillin and Its Derivatives. Confectionery Ingredients, Ltd., F. E. Matthews, and A. T. King, London; and T. Kane, Gaywood, Norfolk. British Patent, 131,161, of 1918.

Vanillin esters and ethers are prepared by treating acyl or aralkyl derivatives of vanilloyl chloride in solution in toluene, xylene, or other inert solvent, at boiling temperature with hydrogen in the presence of an hydrogenating catalyst, such as palladium or nickel, which may be deposited on a carrier, such as barium sulphate or asbestos. Examples are given of the treatment of vanilloyl chloride *p*-toluenesulphonic ester; the acetate, benzoate, and carbonate, and the benzyl ether of vanilloyl chloride are also specified as parent materials. Vanillin is obtained by hydrolysing the esters and ethers in the usual manner. The Provisional Specification also describes the reduction of vanilloyl chloride to vanillin by the process set forth above. The esters and ethers of vanilloyl chloride referred to above may be prepared by treating vanillic acid with acyl or aralkyl chlorides and converting the products into the corresponding chlorides by means of thionyl chloride. According to the Provisional Specification, vanilloyl chloride is prepared by treating an alkali vanillate with thionyl chloride or phosgene.

Wood Distillation. P. Poore, London. British Patent, 131,006, of 1917.

Wood, peat, and other carbonaceous material in small pieces are dried in a kiln by waste gases from a furnace admixed with air, and the dried material is distilled in a retort and subjected to the action of superheated steam, while the products of distillation thus formed are passed to condensers for condensing tar, acetic acid, wood spirit, etc. The superheater is heated by the waste products from the distillation furnace. As shown, a cylindrical retort *b* is heated in a furnace *a* with rails *a*¹ for the retort to be removed for charging through an opening normally closed by a cover

*a*⁷. The flames from the fire pass a damper *a*⁸ and are led by flues *a*² through grids *a*³ and around the retort. Vertical flues *a*⁵ deliver the furnace gases to a superheater *d*, and a pipe *f* carries the gases through a tank *g* with screens *g*² for removing soot,

etc., the gases are mixed with air admitted through a passage *g*⁷ controlled by a damper *g*⁶, and pass through a pipe *g*⁸ to a drying chamber *h* with inclined bottom *h*¹, charging door *h*³, and discharging door *h*⁴. The waste gases and vapour from the chamber *h* are removed by a pipe *h*² and fan *i*. The retort *b* is fitted with covers *b*¹, *b*², and the cover *b*¹ being fitted with an outlet pipe *b*⁴ which is connected by means of a coupling *b*⁵ to a pipe leading to the condenser. Pipes *c*¹, *c*² lead the steam from the superheater *d* into the retort, and this steam is admitted to pass through the wood, etc., after this has been heated in the retort to a temperature of at least 100° C. A number of drying chambers as *h* may lead to one chimney, and means may be provided for by-passing part of the gases from the superheaters, or from the driers, or both. A secondary air supply may be provided at the top of the retort-heating furnace. According to Provisional Specification 13,321/17, baffle-plates or curtains may be provided in the drying-kilns.

Esters. A. Boake, Roberts and Co., Stratford, London; and T. H. Durrans and W. E. Ellis, Oxford. British Patent, 131,088, of 1918.

Esters are prepared by passing the vapours of an alcohol and a fatty acid over a catalyst applied to a suitable support. Suitable catalysts are ortho-, meta-, or pyro-phosphoric acid, sulphuric acid, acid sodium or potassium phosphate or sulphate, and zinc, calcium, or magnesium chloride; suitable supports are pumice, earthenware, coke, or gas-carbon, fire-brick, and asbestos. The application of the catalyst to the support may be effected in the following ways: Pumice is sprinkled with or immersed in sulphuric acid, or coke or gas-carbon is sprinkled with or immersed in ortho-phosphoric acid, and the treated support is then drained and heated to

REPORTS OF COMPANIES.

Ship Canal Portland Cement Manufacturers, Ltd.

The report for the year to March 31 last states that the directors were compelled to pass the half-yearly dividend on the cumulative participating preference shares due on June 1 and December 1, 1918. The restrictions under which the cement industry laboured, described in preceding reports, continued to prevail during the financial year under review. The speedy revival of the cement industry that was anticipated after the signing of the Armistice did not come to pass, attributable mainly to the unsettled labour, transit, and market conditions. For these reasons the raising of the embargo on the export of cement did not assist to the extent expected. The slump in the trade continued up to and after the end of the financial year. However, for some months past the demand has revived, and is being dealt with to the fullest extent that the general conditions prevailing will permit. The indications in all markets point to constantly increasing demand well in excess of the production capacity of the industry, and for a period on which no time-limit can be set. The directors are vigorously pushing forward the extensions to increase the production of cement to over 4,000 tons per week. The directors are also proceeding with the erection of a special installation for the production of carbo limo, and for the production of a new commodity (on account of a firm who are marketing the material under the name of "Rectisoil"), the carrier of which is carbo limo. There are indications of demand for carbo limo for other uses, and the special plant now being erected will, on completion, enable the directors to supply the indicated new outlets. The Board of Trade have granted the necessary order to enable the Mersey Power Company to supply bulk power to this undertaking, and it is hoped that this service will be available by the time the extensions are completed. After charging repairs and renewals to the working account, the directors have written off £10,000. to depreciation, leaving a credit balance of £14,781.; and £6,449. was brought in, making £21,230., which the directors propose to carry forward. To facilitate the company's financial arrangements, the directors entered into an agreement with the British Maritime Trust, Ltd., and to give effect to the conditions of that agreement the capital of the company was increased by the creation of a further 150,000 ordinary shares of £1. each and 1,500 deferred shares of 1s. each. None of these shares has been issued.

Sadler and Co., Ltd.

For the year to June 30, 1918, the net profit rose from £27,004. to £46,754., but in the past twelve months there was a partial setback to £33,045. The reserve for depreciation is again to get £25,000., but the allocation of £2,000. to the reserve is not to be repeated. The ordinary dividend is, however, to be retained at 9 per cent., having been 7 per cent. for 1915-16 and 8 per cent. for 1916-17. The undivided balance will be lowered from £6,825. to £4,221.

Associated Portland Cement Manufacturers (1900), Ltd.

At an extraordinary meeting on October 24, it was decided that all £10. shares in the company should be divided into ten £1. shares and numbered accordingly. It was also decided that the name of the company be changed to the Associated Portland Cement Manufacturers, Ltd.

DIVIDENDS.

MIAMI COPPER COMPANY.—Quarterly dividend of 50 cents per share on capital stock for quarter.

COMING EVENTS.

Society of Public Analysts.—Meeting, Wednesday, November 5, at the Chemical Society's Rooms, Burlington House Piccadilly, W., at 8 p.m. Papers: "Egyptian Bricks," By G. Rudd Thompson, F.I.C.; "The Analysis of Brazilian Zirconium Ore," by A. R. Powell and W. R. Schoeller, Ph.D.; "The Halogen Absorption of Turpentine," by Ethel M. Taylor.

The Institution of Civil Engineers.—Opening meeting, Great George Street, Westminster, S.W. 1, Tuesday, November 4, at 5.30 p.m. Address by Sir John Purser Griffith, the president, and presentation of medals awarded by the Council.

College of Technology, Manchester.—Tuesday, November 4, at 4.30 p.m. Lecture by Mr. W. H. Barnes on "Paint Grinding."

The Technical Inspection Association.—Paper by Professor Baly, C.B.E., F.R.S., on "The Spectroscope in the Science of To-day," at the rooms of the Royal Society of Arts, John Street, Adelphi, Friday, November 7, at 7.30 p.m. ...

The Chemical Society.—Meeting, Burlington House, Piccadilly, London, W. 1, Thursday, November 6, at 8 p.m. Papers: "Equilibria Across a Copper Ferrocyanide and an Amyl Alcohol Membrane," by F. G. Donnan and W. E. Garner; "The Peroxides of Bismuth," by R. R. Le G. Worsley and P. W. Robertson; "The Properties of Ammonium Nitrate—Part I.: The Freezing-point and Transition Temperatures," by T. M. Lowry and R. G. Early; "Organic Derivatives of Tellurium—Part I.: Dimethyl-tellurium-diiodide," by R. H. Vernon; "Intramolecular Rearrangement of the Alkylarylamine: Formation of 4-Amino-n-butylbenzene," by J. Reilly and W. J. Hickinbottom; "A New Modification of 3,4 Dinitro dimethylaniline," by H. Swann; "The Refractivities of Unsaturated Substances," by G. Le Bas; "The Molecular Refractions of Benzene and Aromatic Derivatives," by G. Le Bas; "Some 1 : 3-Benzodiazolecarbinic Acids and Their Reduction Products," by R. R. Baxter and R. G. Fargher.

Society of Chemical Industry: Manchester Section.—Meeting, Grand Hotel, Friday, November 7, at 7 p.m. Papers: "The Estimation of p-Phenylene Diamine," by T. Callan, M.Sc., Ph.D., and J. A. R. Henderson, D.Sc.; "The Estimation of Sulphuric Acids in the Presence of Organic Sulphonic Acids," by T. Callan, M.Sc., Ph.D., J. A. R. Henderson, D.Sc., and R. Barton.

GAZETTE NEWS.

LIMITED COMPANIES.—Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions, Orders, and Official and Other Notices.

Lead Wool Company, Ltd.—Resolved June 18, confirmed July 16: That it is expedient to reconstruct the company, and accordingly that the company be wound up. Alice J. Ball, Snodland, spinster, liquidator.

Wear Portland Cement Company, Ltd.—Resolved October 17: That the company be wound up. H. S. Squance, Sunderland, chartered accountant, liquidator.

British Lead Syndicate, Ltd.—Resolved October 8: That the company be wound up voluntarily. R. Henderson, 198, St. Vincent Street, Glasgow, writer, liquidator. Meeting of creditors at liquidator's, October 24.

DISSOLUTIONS OF PARTNERSHIP.

(Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.)

Primus Edible Products Company (Walter Thos. Balding and Joseph St. Ludger), 9, Broughton Street, Hockley, Birmingham, edible fat manufacturers. April 30. Debts by W. T. Balding, who continues. (October 14.)

Purvis Hopkins and Sons (Hy. Hopkins Purvis and Alb. Hopkins Purvis, 20 and 21, Greek Street, Soho, colour grinders, and white lead, oil, and varnish merchants. December 31, 1918. Debts by A. H. Purvis. (October 17.)

Boyd, Finlay and Co., 36, Salamander Street, Leith, grain, hay, straw, treacle, and chemical manure merchants. May 31, by retiral of Geo. Young Finlay. The business will continue to be carried on by Thos. Geo. Boyd, along with Saml. Carter, 45, Lorne Street, Leith, and Jno. Hunter, 5, Waverley Place, Edinburgh, who have been assumed partners, and under the same name, and they are authorised to uplift all debts due to, and will discharge the whole debts and liabilities of, the firm. (October 14.)

CHEMICAL TRADE INDUSTRIAL COUNCIL.—The first meeting of the North-Western District branch of the Chemical Trade Joint Industrial Council was held in Liverpool on Tuesday, when Mr. Max Muspratt, of the United Alkali Company, Ltd., was appointed chairman, and Mr. R. Hewitt, of the National Union of General Workers, was appointed vice-chairman, with Mr. G. Martyn as secretary. This body consists of an equal number of employers and employed, and covers the whole North-West of England. Regular meetings will be held alternately in Liverpool and Manchester. An emergency committee was also appointed for prompt action between regular meetings.

CORRESPONDENCE.

***We do not hold ourselves responsible for the opinions expressed by our correspondents.*

Malachite Green Crystals.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—In response to the invitation contained in the letter from the British Chemical Trade Association, we have pleasure in drawing your attention to the fact that we have put down certain plant for the manufacture of malachite green. We are increasing this plant and will shortly be in a position to supply most of the ordinary requirements.

As a general comment on the substance of the letter we might say that we do think that the larger dyestuff users have been somewhat harsh in their criticisms of British dyestuff manufacturers, and to some extent the attitude of the users with regard to malachite green as expressed in this letter is a minor example of this.

For instance, in the present case we can assure you that if the users of malachite green had advertised their requirements

in any one of the trade journals at the time when they were badly in need of the colour, or if they had written a letter similar to the present one to one of the trade journals, we would immediately have responded by taking steps to meet their requirements to the best of our ability. However, we find that in general the dyestuff users have been rather apt to turn too readily to Swiss and American products. Of course, we know they have had very extreme difficulties, and we heartily sympathise with them, but it does not seem to have been generally recognised that during the war it was impossible for either British manufacturers, or, indeed, any other manufacturers (not excluding German manufacturers), to produce certain of the dyestuffs that we badly needed.

The reason for this did not lie in any insuperable difficulties in the processes, and was not due to any want of knowledge or experience, but solely to the fact that the Governments of the various countries required the whole of the available supplies of the necessary raw materials for these particular colours for war purposes.

Trusting that this letter may prove of interest to your readers, and assuring you that we shall be at all times pleased to do our utmost to meet the needs of new clients.—Yours, etc.,

THE LONDON DYE MANUFACTURING CO. LTD.,

P. A. LOEBBURY,
Managing Director.

Stratford, London, E. 15, October 24, 1919.

MARKET REPORTS.

TAR AND AMMONIA PRODUCTS.

WEDNESDAY.

Benzole: London, 90%, 2s. to 2s. 1d.; North, 1s. 11d. to 2s.; 50%, 1s. 10d. to 1s. 11d.; North, 1s. 9d. to 1s. 10d., naked; pure, 3s., naked, at works. Carbolic acid, crude, 60%, East and West Coast, nominally 1s. 7d. to 1s. 8d.; crystals, 39-40%, 9½d. to 9d., f.o.b. Crude tar, London, 45s. to 50s.; Midlands, 44s. to 46s.; North, 45s. per ton, ex works. Pitch, 77s. 6d. to 80s.; East Coast, 70s. to 75s., f.o.b.; West Coast, 62s. 6d. to 65s.; f.a.s. Solvent naphtha, naked, London, 90-100%, 2s. 5d.; North, 2s. 3d. to 2s. 4d.; 90-160%, naked, London, 2s. 5d.; North, 2s. 2d. to 2s. 3d. Crude naphtha, naked, 30%, 9d.; North, 8d. to 8½d. Refined naphthaline, £16. to £18.; salts, £6. to £7. Toluol, naked, London, 2s. 6d.; North, 2s. 5d. Creosote, naked, London, 6½d.; North, 5½d. to 5½d.; heavy oil, 6½d. Anthracene, 40-45%, 7d. per unit. Cresylic acid, 95%, 2s. 5d. to 2s. 6d.; 97-99%, 2s. 7d. to 2s. 8d., ex works, London, and f.o.b. other ports. Sulphate of ammonia: home trade, October £20. 10s., November £20. 15s., basis 24½%. Nitrate of soda, £22. to £22. 10s.

FERTILISER MATERIALS.

LIVERPOOL, THURSDAY.

Nitrate of soda continues very steady, the quotation on spot for 95-96% quality being £20. 2s. 6d. per ton, net cash, f.o.r. Liverpool, prompt delivery. East Indian bone meal: Shippers still maintain a firm attitude, the quotation for November-December shipment being £17. 10s. per ton, net cash, ex ship Liverpool, for 4½% ammonia and 52% phosphates. On spot Liverpool, holders require £17. 10s. per ton, net cash, for 4½% and 45% quality. Mineral phosphates: No alteration is to be reported in this market, and values at present are only nominal. Dried blood scarce, the value here being about 30s. per unit of ammonia per ton, net cash.

LONDON METAL MARKET.

THURSDAY.

Copper: Standard brands, £100. to £100. 5s., cash; £100. 15s., three months; electrolytic, £114. to £118. Tin: Standard, £276 15s. to £277., cash; £277. 15s. to £278., three months; Straits, £276. 15s.; English, £276. to £277. Lead: Soft foreign, £30. 10s.; English, £31. 5s. Spelter, £44. 10s.; hard, £31. to £32. Antimony, English regulus, 90%, £47. 10s. Aluminium £150. Nickel £205., delivered; packages extra. Quicksilver, £17. to £17. 5s. Bismuth 12s. 6d. Platinum 442s. per oz. Wolfram 32s. 6d. per unit.

TURPENTINE MARKET REPORT.

Messrs. James Watt and Son, Ltd., of 101, Leadenhall Street, London, E.C. 3, report that the stocks of turpentine on October 25 were: American, 34,261 barrels, compared with 4,086 barrels at the corresponding date of 1918; French, 640

barrels (599 barrels); and Spanish, 382 barrels (1,218 barrels). Deliveries during the week ended October 25 were 1,651 barrels, against 497 barrels last year, and since January 1, 60,843 barrels, compared with 20,725 barrels in 1918. The price on Saturday last was 126s. per cwt., compared with 105s. at the corresponding date of last year. October-December delivery was quoted at 126s. 6d., and January-April (1920) 128s.

MANCHESTER CHEMICAL MARKET.

THURSDAY.

Business in all branches of the trade continues brisk, both on home and export account, and values, as a whole, are well maintained. Caustic soda, 70%, is firmly held for £24. 10s., and in good demand. Bicarbonate of soda, bags, steady at £8. 10s. per ton. Bleaching powder unchanged at £17., on rails makers' works. Chlorate of soda easy at 6d. per lb. Potash quiet at 1s. 1d. per lb. Saltcake firm at 70s., net, per ton, carriage paid, in bulk. Soda crystals, bags, £5. 10s. 6d. per ton, carriage paid. Recovered rock sulphur, £17. per ton, f.o.r. There is no improvement in the position of copper sulphate, and price remains nominal at £40. per ton, f.o.b. Liverpool. Commercial hyposulphite of soda dearer at £19. per ton. Phosphate of soda firm at £27. per ton. Nitrate of soda scarce on the spot at £59., basis 100%. Concentrated sodium sulphide quiet at £22. per ton, in casks. White powdered arsenic continues in short supply, and price firm at £60. per ton. Yellow prussiate of potash slow of sale at 1s. 9d. per lb. Soda in active request, and price higher at 1s. per lb. Solid caustic potash, 88-90%, is now offered at £100. per ton. Carbonate of potash steady at £100. per ton, basis 85%. Lead salts are again quiet, but quotations are steady at £83. for white acetate, £68. for brown, and £54. for nitrate. Acetate of soda and acetic acid are unchanged at recent rates. English brown acetate of lime firm at £12. per ton; grey, £17. per ton; miscible wood naphtha, 10s. 6d. per gallon. Green copperas is in fair demand. Oxalic acid lower at 1s. 1½d. per lb., delivered.

SWANSEA MARKET REPORT.

THURSDAY.

Tinplate prices are exceptionally strong, and have advanced during the week; export prices for prompt delivery are 42s. to 42s. 6d. per standard box, f.o.b. Copper is not so active, and prices have weakened considerably for prompt dealings to £98. 5s. per ton and £99. three months. Tin steady at £273. 10s. cash and £274. 10s. three months. Silver 5s. 5d. per ounce. Lead is easier, with better demand at £29. 17s. 6d. per ton for Spanish and £31. 5s. for English. Zinc sheets steady: English at £65. to £70., and American £65. per ton, f.o.b. New York. Antimony, £47. 10s., f.o.b. Aluminium, £150. Quicksilver, £17. per bottle. Spelter active and somewhat easier at £45. per ton for delivery over November and December. Nickel, £205. per ton, including

delivery. London. Sulphate of copper inactive at £40. per ton for home purposes and £41. for export, less 5% in casks, f.o.b. Sulphate of ammonia steady at £20. 10s. per ton for prompt delivery. Nitrate of soda steady at 21s. 6d. to 22s. 6d. per cwt. for ordinary to refined, in bags. Seed oils firmly held at steady prices. Palm oil quiet. Lagos, £85.; softs, £84. 10s.; Benin, £84.; and hards, £81. 12s. 6d. per ton. Turpentine quietly steady at £6. 7s. per cwt. Arsenic in better demand, with white powdered at £58. 12s. 6d. per ton, in bags, f.o.b. Oxalic acid quiet at 1s. 1d. per lb., f.o.b. Pitch, £3. 3s. per ton, ex ship. Green copperas in good demand at £3. 10s. to £4. per ton, delivered.

LIVERPOOL CHEMICAL MARKET.

THURSDAY.

An active inquiry for chemicals has been experienced through the week to date, the demand on home trade account being brisk, and that on export account having increased. Difficulty has been met with in arranging for deliveries of fresh supplies of some of the heavier goods at early dates, owing to stocks of these goods at works and elsewhere being very small. More interest has consequently been shown in securing supplies for dates some distance ahead with a view to covering prospective requirements. Bleaching powder has been in moderate demand. Prices are: £17. per ton, free on rail or conveyance, in buyers' packages, for the home trade; and £15. to £18. per ton for export. Chloride of calcium has been quiet, and is £8. to £11. per ton, in casks, f.o.r. Caustic soda has been in active demand, and very little of it has been offered. Quotations are: £24. per ton for 76%; £22. per ton for 70 to 72%, and £19. per ton, for 60 to 62%. Nitrate of soda has sold more freely, and is £21. to £22. per ton. Saltcake has been in good request, and is £6. 10s. per ton, in casks, f.o.b. Soda crystals have been in fairly active demand, and are £5. 10s. per ton, in 2cwt. bags, f.o.r. at works. Bicarbonate of soda has sold readily, and is £8. 5s. to £10. per ton, according to terms of delivery. Borax has been in well sustained demand, but scarce. Ordinary is £48. per ton, and powdered, £49. to £50. per ton, in bags. Ammonia alkali has again met with a brisk inquiry, and makers are reported to have well sold their productions for some months to come. Prices may be given as £6. 10s. to £6. 15s. per ton, f.o.r. at works. Hyposulphite has been in moderate request, and is £16. per ton for ordinary, and £21. per ton for pea crystals in 1cwt. bags. Sulphite of sodium has been rather more in demand, and is £10. per ton for ordinary, and £16. to £18. per ton for pea crystals, in 1cwt. kegs. Sulphide of sodium has met with a steady inquiry, and is £20. per ton in casks, and £22. per ton in drums. Prussiate of soda has been in active demand, and is dearer. It is 11d. to 1s. per lb. Bichromate of soda has been in very fair request, and is 9d. per lb. Phosphate of soda has been more inquired for, and is £25. per ton. Chlorate of potash has been in good request, and is 1s. per lb. Permanganate of potash has again been quiet, and is 3s. 3d. per lb. Sulphate of potash has been very quiet, and is £25. per ton. Carbonate of potash has been in moderate request, and is £95. to £100. per ton for 80 to 85%. Caustic potash has been well inquired for, and is £120. per ton. Nitrate of potash has been more called for, and is £55. to £60. per ton for refined, and £40. per ton for ordinary. Canadian potashes have been very quiet. First quality Montreal are £200. to £220. per ton. and second quality, £190. to £210. per ton. Bichromate of potash has been in fair request, and is 1s. 6d. per lb. Yellow prussiate of potash has been more in request, and is 1s. 9d. to 1s. 10d. per lb. Sal ammoniac has been in very fair demand and scarce. Prices may be given as £85. per ton for first quality lump; £80. per ton for second quality, and £5. per ton extra for crushed. Sulphate of ammonia has been more inquired for. Prices are, £20. 15s. per ton for November; £21. for December; £21. 7s. 6d. for January, 1920; £21. 15s. for February, and £22. per ton for March to May, 1920. Carbonate of ammonia has been in fair request, and is 6½d. per lb. Muriate has been but little called for, and is £48. to £50. per ton. Magnesia has been more in demand. Carbonate is £2. 5s. per cwt., and sulphate, £11. to £16. per ton according to grade. Alum has had a rather brisk inquiry, and is still in very small supply. For home trade uses, £18. 10s. per ton is being quoted, and for export, £18. 10s. to £19. 10s. per ton. Aluminoferric has been very quiet, and is £8. 10s. to £12. per ton according to quality. Sulphate of alumina has been but little inquired for, and is £12. to £17. per ton, according to grade. Sulphur has been in moderately active demand, and in short supply. English flowers are £32. per

ton, roll is £28. per ton, and rock £22. per ton, in bags, f.o.r. Sicilian grades are: flowers, £28. per ton; roll, £22. 10s. per ton; and rock, £17. 15s. per ton. Cream of tartar has been in very fair request, and is £12. to £12. 5s. per cwt. Tartaric acid has been steadily called for, and is 3s. 2d. to 3s. 3d. per lb. Boracic acid has been more in request, and has been scarce. Crystals are £80. per ton, and powdered £82. per ton. From £2. to £3. per ton extra is charged for delivery in casks. Oxalic acid has been in quietly steady demand, and is 1s. 1d. to 1s. 2d. per lb. Citric acid has sold more readily, and is 4s. 3d. to 4s. 4d. per lb. White acetate of lead has been but little called for, and is £85. per ton. Arsenic has been rather more in request. White powdered is £58. to £60. per ton. Sulphate of copper continues inactive. From £40. to £41. per ton is quoted for home trade lots, and from £41. to £42. per ton for export; less 5%, in casks, f.o.b. at Liverpool.

TYNE CHEMICAL REPORT.

TUESDAY.

Market very steady, and there is a brisk demand, particularly for caustic soda and bleaching powder, both for home and export. Sulphur continues in good request, and is firm at £22. to £23. per ton at makers' works, in bags. Soda crystals locally are scarce and firm at £5. 10s. per ton, in bags.

The following prices are per ton, net: Bleaching powder, softs, £17.; caustic soda, 76-77%, £24.; do., 74-76%, £23. 10s.; do., 70%, £22. 5s.; do., 60%, £21. 10s.; recovered sulphur, 2cwt. bags, £22.; hyposulphite of soda, 5-7cwt. casks, £19.; do., 1cwt. kegs, £25.; sulphite of soda, 5-7cwt. casks, £12.; do., 1cwt. kegs, £20.; silicate of soda, 75° Tw., £9. 12s. 6d.; do., 100° Tw., £10.; do., 140° Tw., £10. 10s.; soda crystals, 2cwt. bags, £5. 10s.; sulphate of soda (salt-cake), in bulk, £4.; pure white sulphate of alumina, £19. 10s.; blanc fixe, £22.; sulphide of sodium, crystals, £18.; do., refined concentrated solid, 60-62%, £25.; hydrate of barium, crystals, £56.

COALS.—Market is steady, and values are very fully sustained. There is plenty of business available, but merchants are hampered with tonnage difficulties and the question of licences. To-day's quotations: Best Northumbrian steam coal, 95s. to 100s. per ton; do., second qualities, 90s. to 95s.; Northumberland small coals, 75s. to 80s.; do., seconds, 70s. to 72s. 6d.; best Durham gas coals, 80s. to 85s.; do., seconds, 65s. to 75s.; Durham bunker coals, 70s. to 80s.; do., seconds, 65s. to 67s. 6d.; foundry coke, 100s.; gas coke, 95s. to 100s.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Wednesday.

During the past week the demand for heavy chemicals has continued to be fairly good, and, on the whole, prices remain on firm levels. Some bigish orders are reported as having been put through during the week, but the general report from the different firms is that the small bulk parcel is still in most favour. Quotations remain unaltered as follows: Arsenic, £62. per ton, net, Glasgow; bicarbonate of soda, £9. 15s. and £10. 10s. per ton for 6-8 casks and 1cwt. kegs, net, Liverpool; boracic acid crystals, English refined, £72. for 2cwt. bags; and borax crystals, £39. for 2cwt. bags, carriage paid; caustic soda, white, 70-72%, £25. per ton, net, Glasgow; chlorate of potash, 1s. 1d. per lb., net, Glasgow; chlorate of soda, 8d. per lb., net, Glasgow; citric acid, 4s. 4d. per lb., 5%, Glasgow; cream of tartar, 98%, £11 10s. per cwt., net, Glasgow; paraffin wax, U.K. deliveries, 125° 6½d. to 6¼d.; 121-39, 5¼d. to 5½d.; 118-209, 5d.; 110-129, 4d. to 4½d.; and 98-102°, 4d. to 4½d.; sal ammoniac, £80. and £75. per ton, net, any port, for first and second lump respectively; sal ammoniac crystals, £85. per ton, net, Glasgow; saltpetre, £3. net, Glasgow; tartaric acid, 3s. 6d. per lb., 5%, Glasgow.

Among the sea oils, the only alteration in price is in the whale-oil section, where pale variety has advanced from 90s. to 92s. There is a fair quantity of this oil on offer, and the same remark applies to brown at the old quotation of 76s. and black at its previously quoted level of 74s.; while yellow is not on offer. Newfoundland cod continues to go into consumption at 80s., with a good number of buyers coming forward at this price; while pale seal at 96s., and Menhaden at 80s., are also fairly strong features.

In the West of Scotland coal market demand remains steady, and supplies of fuel, on the whole, are to the short side. There are no alterations in prices, and the minimum figures are still according to the schedule issued by the Coal Controller.

Antwerp, 250 t. 13 c., £814.; Bathurst, 3 c., £2.; Grand Bassam, 4 c., £2.; Lagos, 3 t. 9 c., £20.; Monrovia, 11 c., £5.

POTASSIUM BICHROMATE—
Alexandria, 10 t. 16 c., £1,724.; Constantinople, 1 t. 1 c., £166.; Calcutta, 3 t., £25.; Rio de Janeiro, 2 t., £182.; Smyrna, 6 c., £44.

POTASSIUM CARBONATE—
Lisbon, 2 c., £14.

POTASSIUM CHLORIDE—
Kobe, 36 t., £2,208.; Shanghai, 40 t., £2,640.; Vigo, 2 c., £14.

POTASSIUM NITRATE—
Corinto, 3 c., £15.

SALAMMONIAC—
Baltimore, 2 t., £151.; Galatz, 1 t., £55.; Karachi, 7 t. 10 c., £527.; Limassol, 2 c., £7.; Montreal, 1 t. 5 c., £90.; Melbourne, 10 c., £36.; Punta Arenas, 2 c., £15.; Rouen, 5 t. 6 c., £358.; Salonica, 1 t. 1 c., £74.

SALICYLIC ACID—
Genoa, 4 c., £7.

SALTPETRE—
Parahyba, 5 c., £16.; Vigo, 1 t., £54.

SHEEP DIP—
Buenos Ayres, 93 t. 8 c., £3,868.; Cali, 10 c., £21.; Manizales, 16 c., £80.

SOAP—
Accra, 1,200 cs.; Adelaide, 28 bxs.; Alexandria, 12 pkgs., 948 bxs.; Algiers, 5 cs.; Amsterdam, 350 cs.; Antwerp, 23 cs., 6,300 bxs.; Assinie, 50 cs.; Athens, 169 cs.; Attuaboe, 100 bxs.; Bangkok, 16 pkgs.; Belewian, 30 bxs.; Bombay, 968 bxs.; Buenos Ayres, 63 bxs.; Calcutta, 112 bxs.; Colombo, 869 bxs.; Cologne, 425 cs.; Constantinople, 50 cs.; Durban, 452 cs.; Malta, 16 cs.; Martinique, 300 cs.

SOAP

Paphos, 20 pkgs.; Piraeus, 95 bxs.; Rotterdam, 16 bxs.; Salonica, 2,385 bxs.; Santos, 5 bxs.; Saltpond, 200 bxs.; 100 pkgs.; Secondee, 600 bxs.; Sherbro, 12 pkgs.; Sierra Leone, 400 bxs.

SODA ASH

Adelaide, 115 pkgs.; Amsterdam, 230 pkgs.; Algoa Bay, 276 pkgs.; Batavia, 330 pkgs.; Buenos Ayres, 1,513 pkgs.; Bombay, 3,600 pkgs.; Chchofo, 840 pkgs.; Cape Town, 237 pkgs.; Delagoa Bay, 193 pkgs.; Dalny, 5,037 pkgs.; Kobe, 865 pkgs.; Melbourne, 293 pkgs.; Monte Video, 410 pkgs.; Piraeus, 100 pkgs.; Rotterdam, 1,000 pkgs.; Samarang, 272 pkgs.; Shanghai, 582 pkgs.; Soerabaya, 1,775 pkgs.

SODA CRYSTALS—

Bangkok, 16 pkgs.; Batavia, 118 pkgs.; Cape Town, 690 pkgs.; Singapore, 25 pkgs.

SODIUM BICARBONATE

Cape Town, 100 pkgs.; Fremantle, 61 pkgs.; Galatz, 100 pkgs.; Halifax, N.S., 370 pkgs.; Kingston, Ja., 28 pkgs.; Manila, 230 pkgs.; Monte Video, 50 pkgs.; Montreal, 1,314 pkgs.; New York, 30 pkgs.; Piraeus, 34 pkgs.; Rotterdam, 410 pkgs.; Samarang, 80 pkgs.; Secondee, 414 pkgs.; Soerabaya, 50 pkgs.; Stamboul, 400 pkgs.; Smyrna, 20 pkgs.

SODIUM CYANIDE—

Batavia, 25 pkgs.

SODIUM SILICATE

Buenos Ayres, 476 pkgs.; Delagoa Bay, 83 pkgs.; Melbourne, 387 pkgs.; Montreal, 32 pkgs.; Piraeus, 63 pkgs.; Porto Alegre, 157 pkgs.; Santos, 317 pkgs.; Shanghai, 240 pkgs.; Sydney, 48 pkgs.

SULPHUR—

La Union, 1 c., £13.; Maranhao, 1 c., £8.

SULPHUR FLOWERS—

Ceara, 1 c., £8.; Corinto, 3 c., £20.

SULPHURIC ACID—

Maranhao, 7 c., £15.

SUPERPHOSPHATE OF LIME—

Las Palmas, 10 t.

TARTARIC ACID—

Christiania, 4 c., £68.; Lima, 4 c., £72.; Punta Arenas, 1 c., £35.

WHITE LEAD—

Lisbon, 3 t.

ZINC CHLORIDE—

Alexandria, 9 t. 13 c., £500.; Bombay, 9 t. 15 c., £422.; Sydney, 1 c., £47.

ZINC PERCHLORIDE—

Copenhagen, 5 c., £65.

ZINC SULPHATE—

Buenos Ayres, 1 c., £8.; Quebec, 2 c., £33.

LONDON.

Week ending October 22.

ACETANILID—

Odessa, 2 cks., £24.; Rostoff-on-Don, 1 c., £19.; Shanghai, 1 c., £7.

ACETIC ACID

Launceston, 2 cks., £6.; Melbourne, 5 cks., £13.; Pt. Moresby, 10 cks., £20.; Suva, 2 cks., £14.; Sydney, 18 cks., £56.

ACETIC ANHYDRIDE—

Melbourne, 3 cks., £14.

ACETO SALICYLIC ACID

Cape Town, 1 c., £11.; Fiume, 7 cks., £359.; Fremantle, 1 c., £12.; Melbourne, 5 cks., £122.; Novorossisk, 3 cks., £119.; Naples, 1 c., £39.; Sydney, 5 cks., £115.

ALUM

Brussels, 5 c., £9.; Calcutta, 5 c., £12.; Lisbon, 2 c., £8.

ALUMINA SULPHATE

Christiania, 6 c., £19.

AMMONIA

Alexandria, 2 drms., £5.; Bilbao, 1 c., £9.; Boulogne, 28 drms., £250.; Bombay, 18 cks., £36.; Calcutta, 5 cks., £10.; Buenos Ayres, 20 cks., £39.; Cape Town, 5 cks., £10.; Demerara, 6 cks., £8.; Durban, 5 cks., £10.; East London, 4 cks., £8.; Lisbon, 20 cks., £39.; Pelotas, 5 cks., £6.; Pt. Elizabeth, 1 c., £8.; Shanghai, 5 cks., £10.

AMMONIUM BIPHOSPHATE

Amsterdam, 1 c., £40.

AMMONIUM BROMIDE—

Shanghai, 1 c., £8.

AMMONIUM CARBONATE—

Bangkok, 9 c., £35.; Cape Town, 11 c., £41.; Charkoff, 10 c., £45.; Constantinople, 1 t., £85.; Hiogo, 10 t., £598.; Hong Kong, 1 c., £7.; Pelotas, 4 c., £19.; Penang, 9 c., £35.

AMMONIUM CHLORIDE

Calcutta, 1 c., £14.; Christchurch, 5 cks., £16.; East London, 2 kgs., £6.; Lyttleton, 2 cks., £29.; Pelotas, 1 c., £28.; Shanghai, 4 cks., £17.; Wellington, 2 kgs., £6.

AMMONIUM CHLOROHYDRATE

Rio de Janeiro, 1 c., £8.

AMMONIUM HYDRATE

Shanghai, 1 c., £11.

AMMONIUM NITRATE—

Antwerp, 11 t., £297.

AMMONIUM SULPHATE—

Dunkirk, 150 t., £3,550.; Paris, 400 t., £10,600.

AMMONIUM SULPHOCYANIDE—

Philadelphia, 1 c., £8.

AMMONIUM VALERIANATE—

Constantinople, 1 c., £10.

AMYL ACETATE—

Brussels, 3 drms., £328.; Paris, 7 drms., £112.

ANTIMONY SULPHIDE—

Dunkirk, 2 pkgs., £44.

ARSENIC

East London, 10 c., £35.; Karachi, 2 t., £140.

BARIUM NITRATE—

Bombay, 20 drms., £50.

BISMUTH

Pelotas, 1 c., £7.; Shanghai, 1 c., 4 cks., £111.

BISMUTH CARBONATE—

Auckland, 14 cks., £11.; Constantinople, 1 c., £17.; Durban, 1 c., £13.

BISMUTH CITRATE—

Constantinople, 7 cks., £25.

BISMUTH OXIDE—

Constantinople, 7 cks., £10.

BISMUTH SALICYLATE—

Constantinople, 7 cks., £77.

BISMUTH SALTS—

Beyrout, 1 c., £5.

BISMUTH SUBNITRATE—

Constantinople, 7 cks., £303.; Sydney, 4 pkgs., £9.

BORAX—

Cape Town, 15 c., £30.; Durban, 2 c., £8.; Malta, 10 c., £20.; Santos, 25 t., £975.

BORIC ACID—

Calcutta (F.), 4 c., £15.; Cape Town, 1 c., £5.; East London, 5 c., £20.; Lisbon, 5 c., £14.; Medan Deli, 2 c., £15.; Piraeus, 1 c., £5.; Rio de Janeiro, 2 c., £13.; Shanghai, 12 c., £45.; Suva, 1 c., £5.

BUTYL ACETATE—

Paris, 1 dm., £11.

CABLE WAX—

Antwerp, 1 t.

CALCIUM & SODIUM HYPOPHOSPHITE

Paris, 10 cks., £244.

CALCIUM CARBIDE

Kalundini, 16 c., £56.

CALCIUM LACTATE—

Lyttleton, 1 c., £6.

CAMPHOR

Marseilles,

CARNAUBA WAX

Abo, 1 t., £18.

CAUSTIC POTASH—

Alexandria, 1 c., 2 cks., £37.

CAUSTIC SODA

Brussels, 25 t. 2 c., £451.

CERESINE WAX

Amsterdam, 10 c.; Antwerp, 1 t. 10 c.; Dunkirk, 1 t.; Melbourne, 5 c.

CHEMICALS (otherwise undesignated)

Aden, 2 cks., £13.; Bombay, 3 cks., £41.; Calcutta, 1 c., £8.; Canton, 2 cks., £19.; Cape Town, 2 cks., £48.; Christchurch, 2 cks., £22.; Dunedin, 2 cks., £70.; Malta, 2 cks., £24.; Melbourne, 4 cks., £77.; Pt. Elizabeth, 3 cks., £34.; Salonica, 1 c., £21.; Sydney, 1 c., £34.; Wellington, 10 cks., £179.

CHINA CLAY—

Bombay, 25 t.

CITRATE OF IRON

Buenos Ayres, 4 cks., £61.

CITRIC ACID—

Barcelona, 2 t., £838.; Brisbane, 1 c., £12.; Cape Town, 5 c., £114.; Charkoff, 10 c., £247.; Christiania, 1 c., £23.; Constantinople, 2 t. 10 c., £1,250.; Montreal, 1 t. 5 c., £565.; Mormugao (F.), 1 c., £6.; New York, 5 t., £2,239.; Pt. Elizabeth, 2 c., £45.; Rangoon, 1 c., £19.; Shanghai, 5 c., £119.; Toronto, 10 c., £226.

COAL PRODUCTS—

Alizarine
Bombay, 4 cks., £118.; Madras, 100 cks., £3,182.; Tuticorin, 3 cks., £118.

Aniline Colour

Bombay, 1 dm., £48.; Brussels, 1 c., £57.

Aniline Dye

Gothenburg, 10 kgs., £434.; New York, 2 cks., £40.; Paris, 1 pcl., £18.; Perth, 1 c., £11.

Aniline Oil

Rotterdam, 1 dm., £50.

Betanaphthol

Amsterdam, 1 brl., £25.; Rotterdam, 1 kg., £20.

Carbolic Acid

Beira, 2 cks., £5.; Kobe, 311 pkgs., £2,966.; Melbourne, 49 drms., £44.; Sydney, 4 pkgs., £5.

Creosote

Gothenburg, 750 brls., £1,294.

Cresylic Acid

Montreal, 10 cks., £89.

Naphtha (Solvent)

Dieppe, 15 drms., £250.

Naphthalene

Calcutta, 59 cks., £199.; Cape Town, 1 c., £5.; Hong Kong, 1 c., £19.; Novorossisk, 38 cks., £180.; Tientsin, 69 cks., £135.

Paranitraniline

Rotterdam, 1 kg., £20.

Pitch

Alexandria, 500 cks., £305.; Calais, 160 t., £548.

Pyridine

Piraeus, 21 drms., £732.

Tar

Beira, 20 drms., £9.; Cape Town, 60 drms., £8.; Penang, 38 cks., £66.

COPPER SULPHATE—

Christiania, 2 t., £80.

CREAM OF TARTAR

Auckland, 2 t., £431.; Beira (F.), 1 c., £17.; Buenos Ayres (F.), 1 c., £11.; Durban, 1 c., £12.; Durban (F.), 2 c., £26.; East London, 4 c., £44.

DISINFECTANTS (otherwise undesignated)

Antwerp, 4 t. 19 c., £265.; Auckland, 8 c., £27.; Beira, 1 c., £7.; Bombay, 13 c., £43.; Calcutta, 2 c., £7.; Canton, 2 c., £12.; Cape Town, 2 c., £6.

DISINFECTANTS (otherwise undesignated)

Colombo, 7 c., £24.; Dar-es-Salaam, 9 c., £18.; Dominica, 2 c., £6.; Durban, 1 t. 6 c., £69.; East London, 1 c., £8.; Fremantle, 1 c., £11.; Hong Kong, 1 c., £6.; Limon, 11 c., £33.; Penang, 1 t. 1 c., £48.; Pt. Elizabeth, 2 t. 6 c., £100.; St. Lucia, 2 c., £3.; Shanghai, 1 t. 19 c., £60.; Suva, 1 c., £8.; Toronto, 1 t. 2 c., £60.

ETHER—

Alexandria, 7 cks., £63.

ETHER (METHYLIC)—

Hong Kong, 4 drms., £14.

ETHER (SULPHURIC)—

Pelotas, 3 cks., £12.

ETHER (SULPHURIC AND METHYLIC)—

Alexandria, 1 c., £8.

ETHYL CHLORIDE—

Toronto, 1 c., £38.; Vancouver, 2 cks., £76.; Winnipeg, 1 c., £38.

FATTY ACIDS—

Trieste, £1,730.

FORMALDEHYDE—

Alexandria (F.), 6 cks., £8.; Trinidad, 3 brls., £83.

GELATINE

Moji, 3 c.

GLUE, SIZE, AND GELATINE

Alexandria, 2 t.; Antwerp, 13 t. 13 c.; Auckland, 11 c.; Bombay, 1 t. 10 c.; Boulogne, 5 c.; Buenos Ayres, 4 c.; Callao, 18 c.; Cape Town, 2 c.; Calcutta, 1 c.; Constantinople, 4 c.; Durban, 5 c.; East London, 2 c.; Fiume, 5 t.; Jaffa, 1 t.; Karachi, 1 t.; Malta, 1 t.; Montreal, 9 c.; Ostend, 4 c.; Osaka, 5 t. 8 c.; Rotterdam, 18 t.; Yokohama, 21 t. 12 c.

GLYCERINE

Buenos Ayres, 1 c., £8.; Shanghai, 2 c., £14.

GLYCEROPHOSPHORIC ACID—

East London, 1 c., £15.; Sydney, 1 c., £27.

HYDROCHLORIC ACID

Jamaica, 1 c., £5.

HYDROCYANIC ACID

Brisbane, 1 c., £16.

HYDROFLUORIC ACID—

Tokio, 5 cks., £17.

HYDROGEN PEROXIDE—

Alexandria, 5 cks., £28.

HYPOPHOSPHITE SALTS—

Paris, 3 cks., £42.

HYPOPHOSPHORIC ACID

East London, 1 c., £5.

HYPOPHOSPHOROUS ACID—

Melbourne, 1 c., £9.

IODINE (RESUBLIMED)

Calcutta, 1 c., £26.; Lisbon, 2 cks., £88.; Shanghai, 1 c., £51.

IRON & AMMONIUM CITRATE—

Brussels, 1 c., £11.; Fremantle, 2 cks., £26.; Toronto, 1 c., £10.

IRON & POTASSIUM TARTRATE

Constantinople, 1 c., £8.

IRON LACTATE—

Alexandria, 1 c., £30.

IRON PERCHLORIDE—

Bombay, 2 cks., £8.

IRON REDACTATE—

Calcutta, 1 c., £8.

LACTIC ACID—

Adelaide (F.), 1 c., £20.; Calcutta, 6 cks., £16.; Fiume, 1 c., £7.; Havre, 10 cks., £160.

LEAD ACETATE—

Auckland, 1 c., £7.; Calcutta, 1 c., £10.

LITHIUM BENZOATE—

Brussels, 1 c., £5.

MAGNESIA—

Adelaide, 20 cks., £59.; Brussels, 1 c., £5.; Pt. Elizabeth, 1 c., £49.

MAGNESIA (CALCINED)

Launceston, 1 c., £5.

MAGNESIUM CARBONATE—

Cape Town, 1 ck., £5.; Otago, 3 cs., £15.; Sydney, 6 cs., £29.

MAGNESIUM CITRATE—

Auckland, 13 cs., £56.; Cape Town, 1 cs., £42.; East London, 1 cs. (pt.), £7.

MAGNESIUM SULPHATE—

Bombay, 4 c., £7.; Canton, 13 c., £25.; Cape Town, 10 c., £11.; Delagoa Bay, 5 c., £11.; Durban, 10 c., £22.; Lourenco Marques, 3 c., £7.; Melbourne, 8 c., £52.; Porto Alegre, 4 c., £12.; Pt. Said, 1 t., £51.; Sydney, 4 t. 18 c., £200.

MANGANESE DIOXIDE—

Auckland, 1 ck., £8.

MERCURIALS—

Constantinople, 2 cs., £79.

METHYLIC ALCOHOL—

Oran, 5 drms., £215.

METHYL SALICYLATE—

Constantinople (F.), 1 cs., 40 drms., 50 cs. (pt.), £493.; East London, 1 dr., £10.

MINERAL WAX—

Buenos Ayres, 16 c.; Malta, 4 c.; Valparaiso, 1 t.

MURIATIC ACID—

Jaffa, 1 c., £8.

NICKEL SULPHATE—

Sydney, 1 ck., £8.

NITRIC ACID—

Jamaica, 1 c., £5.; Malta, 2 c., £6.

OXALIC ACID—

Calcutta, 1 ck., £9.

PARAFFIN WAX—

Batoum, 2 t.; Lyttleton, 1 t. 13 c.

PHENYL ACETALDEHYDE—

Melbourne, 1 cs. (pt.), £7.

PHOSPHORIC ACID—

Amsterdam, 1 crby., £9.; Cape Town, 2 cs., £10.; Melbourne, 7 cs., £41.; Paris, 15 crbys., £146.; Sydney, 5 cs., £45.; 89 cs., £374.; Swatow, 1 cs., £10.

PLUMBAGO—

Bombay, 11 t.; Cape Town, 5 t. 7 c.; Genoa, 1 t. 13 c.; Piraeus, 2 t.

POTASSIUM ACETATE—

Christiania, 2 cs. (pt.), £17.

POTASSIUM BICARBONATE—

Christchurch, 1 cs., £10.

POTASSIUM BICHROMATE—

Auckland, 1 c., £11.

POTASSIUM BISULPHITE—

Paris, 6 cks., £68.

POTASSIUM BITARTRATE—

Constantinople, 1 cs. (pt.), £12.

POTASSIUM BROMIDE—

Bombay, 2 cs., £55.; Shanghai, 3 cs. (pt.), £11.

POTASSIUM CARBONATE—

Alexandria, 1 cs., £18.; Calcutta, 1 cs., £11.

POTASSIUM CHLORATE—

Cyprus, 1 cs., £9.

POTASSIUM CITRATE—

Montreal, 2 cs. (pt.), £25.; Toronto, 1 cs., £23.

POTASSIUM CYANIDE—

Buenos Ayres, 4 cs., £49.; Calcutta, 1 cs. (pt.), £14.; Odessa, 3 cs., £120.; Shanghai, 4 cs., £70.

POTASSIUM IODIDE—

Calcutta, 1 ck. (pt.), £87.; Melbourne, 1 cs. (pt.), £2.; Shanghai, 1 cs., 3 cs. (pt.), £107.

POTASSIUM PRUSSATE—

Fremantle, 1 kg., £10.; Sydney, 1 kg., £34.

POTASSIUM SULPHIDE—

Rio de Janeiro, 1 ck., £19.

POTASSIUM SULPHOGUAICO-

LATE—
Buenos Ayres, 1 cs. (pt.), £50.; Christiania (F.), 1 cs. (pt.), £30.; Constantinople (F.), 2 cs. (pt.), £150.

POTASSIUM TARTRATE—

Buenos Ayres (F.), 2 c., £76.; Calcutta, 1 c., £31.; Stockholm, 1 cs., £10.

PYRAMIDON—

B. Ayres (F.), 1 cs. (pt.), £44.

QUININE—

Calcutta, 9,000 ozs.; Cape Town, 30 ozs.; Karachi, 1,200 ozs.

ROCHELLE SALTS—

Habana, 1 t., £140.

SALAMMONIAC—

Amsterdam, 3 c., £12.

SALICYLIC ACID—

Auckland, 1 cs., £13.; Cape Town, 1 cs. (pt.), £11.; Launceston (F.), 1 cs. (pt.), £5.; Naples, 1 cs., 2 cs. (pt.), £66.

SALT—

Auckland, 20 t.; Copenhagen, 4 c.; Lyttleton, 90 t.

SALTPETRE—

Bilbao, 10 c., £26.; Durban, 10 c., £32.; Eten, 10 c., £31.; East London, 9 c., £28.

SHEEP DIP—

Buenos Ayres, 15 t., £600.; Delagoa Bay, 2 t. 7 c., £86.; Durban, 9 t. 9 c., £401.; Pt. Elizabeth, 1 t. 18 c., £86.

SILVER NITRATE—

Beyrout, 2 cs. (pt.), £24.; Constantinople, 1 cs. (pt.), £55.; Durban, 6 cs. (pt.), £18.; Cape Town, 1 cs. (pt.), £9.

SILVER PROTEINATE—

Constantinople, 1 cs., 1 cs. (pt.), £96.

SOAP—

Aleppo, 8 c.; Alexandria, 4 t. 5 c.; Amsterdam, 17 c.; Amoy, 2 c.; Antwerp, 216 t. 8 c.; Auckland, 9 c.; Barbados, 1 c.; Beira, 1 c.; Bilbao, 13 c.; Boston, 1 t. 5 c.; Bombay, 10 t. 14 c.; Boulogne, 52 t. 3 c.; Brisbane, 10 c.; Buenos Ayres, 1 c.; Canterbury, 1 c.; Calcutta, 3 t. 7 c.; Cape Town, 4 c.; Chinde, 1 t. 5 c.; Cologne, 168 t. 2 c.; Colombo, 7 t. 8 c.; Delagoa Bay, 1 c.; Damerara, 4 c.; Durban, 1 t. 4 c.; Fiume, 30 t. 15 c.; Galatz, 19 c.; Genoa, 1 t. 16 c.; Gibraltar, 6 c.; Halifax, 10 c.; Helsingfors, 50 t.; Hong Kong, 1 t. 2 c.; Jaffa, 3 c.; Jamaica, 8 c.; Launceston, 4 c.; Lisbon, 2 c.; Marseilles, 22 t. 10 c.; Madras, 15 c.; Montreal, 9 c.; Mazagan, 17 t.; Mozambique, 4 c.; Melbourne, 8 c.; Nantes, 4 c.; Naples, 1 t. 8 c.; New Plymouth, 3 c.; Ostend, 12 t.; Pt. Elizabeth, 1 c.; Pt. Said, 1 c.; Rotterdam, 19 t. 11 c.; Seychelles, 2 c.; Shanghai, 6 c.; Singapore, 13 c.; St. John, N.B., 7 c.; Sydney, 4 c.; Toronto, 5 t. 9 c.; Trinidad, 1 t. 2 c.

SODA (CALCINED)—

Pt. Said, 6 c., £6.

SODIUM AND POTASSIUM TAR-

TRATE—
Constantinople, 1 cs. (pt.), £7.

SODIUM BENZOATE—

Buenos Ayres, 1 cs. (pt.), £9.; Pelotas, 1 cs., £25.

SODIUM BICARBONATE—

Cape Town, 8 c., £15.; Delagoa Bay, 3 c., £6.; Durban, 10 c., £10.; Hankow, 12 c., £9.; Smyrna, 6 c., £15.; Toronto, 5 c., £12.

SODIUM BISULPHATE—

Piraeus, 1 t., £7.

SODIUM BISULPHITE—

Bombay, 1 t., £32.; Paris, 18 c., £26.; Penang, 2 t. 10 c., £75.; Pt. Swettenham, 1 t. 5 c., £38.; Singapore, 1 t. 5 c., £38.

SODIUM BROMIDE—

Calcutta, 1 cs., £7.; Launceston (F.), 1 cs. (pt.), £7.

SODIUM CACODYLATE—

Buenos Ayres, 1 cs. (pt.), £10.

SODIUM CARBONATE—

Salonica, 2 c., £7.

SODIUM CITRATE—

Montreal, 2 cs. (pt.), £21.

SODIUM CYANIDE—

Delagoa Bay, 32 t., £2,990.

SODIUM HYDRATE—

Alexandria, 6 cs. (pt.), £7.

SODIUM HYPO—

Bombay, 2 t. 10 c., £75.; Hong Kong, 8 c., £12.; Penang, 1 t., £28.; Pelotas, 4 c., £22.; Rio de Janeiro, 1 t. 19 c., £49.; Salonica, 1 t., £29.

SODIUM IODIDE—

Calcutta, 1 cs. (pt.), £23.

SODIUM METABISULPHITE—

Nantes, 5 c., £13.

SODIUM NITRATE—

Bombay, 20 drms., £92.; Cyprus, 1 cs. (pt.), £11.

SODIUM OXALATE—

Brisbane, 1 t., £215.

SODIUM PHOSPHATE—

Amsterdam, 14 c., £88.; Christiania, 2 c., £13.

SODIUM PRUSSATE—

Montreal, 9 t. 19 c., £928.; New York, 40 t., £2,265.; Tokio, 20 t., £1,352.

SODIUM PYROPHOSPHATE—

Sydney, 1 t. 3 c., £123.

SODIUM SALICYLATE—

Buenos Ayres, 1 cs. (pt.), £5.; Melbourne, 1 cs. (pt.), £12.; Naples, 1 cs. (pt.), £13.

SODIUM SULPHATE (GLAUBER

SALTS)—
Brisbane, 1 t. 2 c., £12.

SODIUM SULPHITE—

Brussels, 2 c., £7.; Bombay, 12 cs., £43.; New York, 1 t. 1 c., £28.; Penang, 1 t., £25.; Salonica, 2 c., £9.

SODIUM TARTRATE—

Calcutta, 1 c., £6.; Lisbon, 1 c., £5.

SODIUM THEOBROMINE—

Fiume, 4 cs., £178.

SULPHATE OF QUININE—

Genoa, 2,999 ozs.

SULPHUR—

Constantinople, 12 c., £30.; Helsingfors (F.), 10 t., £253.; Piraeus, 10 c., £21.; Suva, 2 c., £6.

SULPHUR (FLOWERS)—

Helsingfors, 5 t., £180.

SULPHURIC ACID—

Alexandria, 1 t., £33.; Jamaica, 1 c., £5.; Pelotas, 1 c., £5.; St. Lucia, 1 c., £7.

TALLOW—

Nantes, 14 t.; Trieste, 180 t.

TANNIC ACID—

Buenos Ayres (F.), 1 cs., £37.; Christiania (F.), 1 cs. (pt.), £18.

TAR (STOCKHOLM)—

Singapore, £314.

TARTARIC ACID—

Auckland, 1 t. 3 c., £352.; Cape Town, 11 c., £191.; Christiania, 2 c., £34.; Durban, 3 c., £46.; Durban (F.), 1 c., £12.; Galatz, (F.), 2 t., £750.; Klang, 2 c., £50.; Lyttleton, 1 t. 13 c., £504.; Melbourne, 2 t. 10 c., £731.; Montreal, 6 t., £1,862.; Mormugao (F.), 1 cs. (pt.), £6.; New York, 4 t., £1,228.; Rangoon, 1 c., £10.; Shanghai, 1 cs. (pt.), £10.

THEOBROMINE—

Beyrout, 1 cs. (pt.), £11.; Buenos Ayres, 1 cs. (pt.), £15.

TIN SALTS—

Antwerp, 1 brl., £36.

WAX—

Gothenburg, 1 t. 5 c.; Malta, 13 c.

WHITE LEAD—

Auckland, £24.; Barbados, £17.; Dunkirk, £650.; Ostend, £378.; Rangoon, £91.; Shanghai, £2,345.; St. Kitts, £32.; Wellington, £56.

ZINC CHLORIDE—

Sydney, 1 cs., £15.

MANCHESTER.

Week ending October 25.

ALUM (GROUND)—

Montreal, 571 bgs.

ALUM (LUMP)—

Alexandria, 45 brls.; Quebec, 140 pkgs.

ALUMINA SULPHATE—

Montreal, 924 sks.

AMMONIA—

Bordeaux, 28 drms.

ANTIMONY SALTS—

Gothenburg, 10 cs.

BLEACHING POWDER—

Gothenburg, 211 cks.; Montreal, 106 pkgs.

CAUSTIC SODA—

Alexandria, 293 pkgs.

COAL PRODUCTS (otherwise undes.)

Antwerp, £1,700.; Dunkirk, £235. Tonnay, £2,600.

COAL PRODUCTS—

Carbolic Acid

Boston, 49 cks.

DISINFECTANTS (otherwise undes.)

Montreal, 355 pkgs.

MAGNESIA—

Alexandria, 2 cs.

MAGNESITE—

Malmö, 100 bgs.

MANGANESE SULPHATE—

Philadelphia, 20 cks.

SALT—

St. John, N.B., 9,870 sks.; Malmö, 2,670 sks.; Quebec, 6,400 sks.

SOAP—

Bordeaux, 10 cs., 1 ck.; Montreal, 7 cks.

SODA ASH—

Montreal, 400 cks.

SODA CRYSTALS—

Alexandria, 5 pkgs.

SODIUM BICARBONATE—

Antwerp, 300 bgs.; Rotterdam, 50 bgs.

SODIUM HYDROSULPHATE—

Philadelphia, 50 kgs.

SODIUM PRUSSATE—

Boston, 25 cks.; Montreal, 5 cks.; Philadelphia, 32 cks.

SODIUM SULPHIDE—

Bordeaux, 123 drms.

MIDDLESBROUGH.

Week ending October 25.

ALUMINA SULPHATE—

Melbourne, 1 t.

CHROME ORE—

Rotterdam, 1 t.

COAL PRODUCTS—

Benzole

Rotterdam, 10 t., £255.

Naphthalene

Fremantle, 2 t., £36.; Melbourne, 21 t., £366.; Natal, 2 t., £37.; Sydney, 8 t., £154.

PITCH—

Antwerp, 1,149 t., £3,735.; Rotterdam, 1,624 t., £5,278.; Santander, 2,244 t., £7,294.

WOOD PRESERVATIVE—

Bulawayo, 8 c., £17.

NEWCASTLE-ON-TYNE

Week ending October 25.

BEESWAX—

Bergen, 1 t.

RED LEAD—

Bergen, 1 t.

N. & S. SHIELDS.

Week ending October 25.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage, are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers)	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—

"Trepex, London." "Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

Trade Advertisements, Announcements, in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

EDITORIAL NOTICES.

Readers are invited to forward items of intelligence, company reports and balance-sheets, or cuttings from local newspapers of interest to the trades concerned.

CURRENT TOPICS

INVIGORATING THE CHEMICAL INDUSTRY.

MR. H. B. FERGUSON, at the annual dinner of the Chemical Industry Club, in London, placed his finger on several weak spots in the organisation of the British chemical industry. The weaknesses which he discussed are not new ones—they have been written about and talked about times without number, and for a good many years—but on the accepted principle that reiteration, to the point of becoming wearisome, is essential before reforms are brought about, Mr. Ferguson's remarks may be productive of some good. That there is need for the application of new methods and new ideas in the conduct of the chemical industry, and for that matter in most other branches of industry, in order to meet the rapidly changing conditions, no one will dispute. As far as the chemical industry is concerned, that fact is recognised clearly enough by chemical manufacturers themselves. Indeed, in many cases the remedies that are being urged upon them are already being applied, but generally the rate of application is much too slow. Unless the reforms from within are greatly accelerated, manufacturers will find themselves in the rear by the time conditions are such as to permit the forces of international competition in the markets of the world to have free play. A point which the speaker particularly emphasised, and justifiably so, was the fact that British manufacturers had been held back by the attempt to organise the industry with the aid of men who were not chemists. In that statement he was supported by Mr. John Gray, the President of the Society of Chemical Industry. It has often been said of chemists in the past that they were incapable of carrying out work of an administrative character. This reproach could hardly have been based on proved incapacity, for the simple reason that few chemists have had the opportunity to prove the contrary. Where such an experiment has been made it has invariably been with advantageous results. In Germany such a system is, and has been for years, the rule rather than the exception, and to this fact alone is due largely the extremely prosperous position of the German chemical industries. Only by widening the sphere of the chemist's activities, and by offering him some greater inducement

than has hitherto been his lot, will the maximum benefits from the application of science to industry be forthcoming.

TECHNICAL RECORDS OF GOVERNMENT FACTORIES.

IN the work of organising the Government factories which during the war were devoted to the manufacture of explosive materials, a very considerable amount of valuable data relating to the processes in operation was collected and utilised for the purpose of effecting economical working. Some of that information has already been made public, and formed the subject of an article which appeared in these columns in our issues of February 8, 15, and 22 last. That information is now supplemented by a report issued by the Department of Explosives Supply of the Ministry of Munitions. An account is given of the statistics of explosive manufacture as developed by the Factories branch of the Department. The statistics are considered from two points of view, the first being the plant or technical aspect, and the second the costing aspect. In connection with the first, the records of plant working are dealt with, and the methods of summarising these in order to ascertain the efficiencies of the plants and the consumption of raw materials; while under the second are considered the methods of finding the actual costs of the finished product, as well as the cost on a comparative basis. The report is divided into the following sections: (1) The material manufactured by the factories, and a general account of the processes involved; (2) the technical aspect of acids manufacture and treatment, and the technical records concerned therewith; (3) the actual costs records dealing with acids manufacture and recovery; (4) the comparative costs for acids; (5) the manufacture of explosives such as nitroglycerine, nitrocellulose, TNT, cordite, picric acid, phenol, etc., with the technical records involved; (6) the method of finding the actual costs of these substances; (7) flow-sheets showing the efficiencies of plants and the consumption of materials involved in these manufactures; and (8) comparative costs. The ground covered is thus very wide, and many of the sections should be of much interest to readers in the chemical industries. These will be dealt with at length in our next issue.

SYNTHETIC AMMONIA.

THE belated and much discussed report of the Nitrogen Products Committee, appointed in 1916 by the then Minister of Munitions, is, according to an announcement made this week, to be issued shortly. The appearance of this document may to a large extent help to clear up the mystery which for some reason or other has been attached to the operations of the Ministry of Munitions in connection with the fixation of atmospheric nitrogen. For the present we must content ourselves with the statement made that there is now reason to judge that by a modification of the scheme which the Ministry had adopted, the production of synthetic ammonia is commercially practicable. A further point, and one which should cause some little satisfaction, is that the Government have decided that further development should be left to private enterprise.

COLORIMETRY IN TECHNICAL ANALYSIS.

A MEETING of the Newcastle and District Section of the National Association of Industrial Chemists was held on Saturday last under the chairmanship of Mr. J. W. Martindale, B.Sc. A paper on "Colorimetry in Technical Analysis" was read by Mr. E. Turner, B.Sc.

Mr. Turner said the colorimetric method of technical analysis was employed almost exclusively in the determination of extremely minute quantities of substances, and consequently was bound to be one of strictest accuracy. He claimed that colorimetry was not only accurate but direct in result. As it was frequently only a matter of matching a colour against a standard and the multiplying of the standard equivalent by a simple multiple it would be seen that the result was quickly gained. There were three ways of carrying out tests colorimetrically. When the colour could be obtained upon a strip of paper it was better to match the colour obtained against a series of standards previously prepared. Where the colour could not be obtained in that way, but only in solution, the method adopted was to obtain a colour with certain quantities of reagents and the test substance; then, using the same quantities of reagents another solution was prepared without any test substance. A standard solution of test substance was then added to the second substance until a depth of colour similar to the first was obtained. The amount of substance in the standard solution added was the required test. The third method involved the use of colorimeters, and of those he considered the Mills to be by far the best and most extensively employed.

Dealing with the conditions necessary to the successful application of colorimetry, Mr. Turner said that colorimetry was founded on the fact that selective colour absorption was constant in a given substance so long as the physical and other conditions remained unchanged. The conditions were a normal light, a common colour standard, a normal vision, and a substance with a characteristic colour. Normal light was made up of the six spectrum colours, and daylight was the nearest approach to that. Diffused daylight enabled determinations to be made with greater accuracy than bright sunlight. The use of the Lovibond chart was of great assistance in describing by letter and number the exact shade and tint of colour obtained. It was obvious that normal vision was necessary, although an experimenter suffering from colour-blindness to a limited degree might carry out useful work providing his infirmity remained unchanged. He added that it was important to take into account the colour given by the water used to effect a solution. An interesting description of apparatus, illustrated by diagrams, followed before Mr. Turner proceeded with the application of colorimetry. One of the most important colorimetric tests in an alkali works was the estimation of arsenic in rectified oil of vitriol. The three methods of estimating arsenic were by Marsh's test, which was accurate, though long and tedious; the production of arsenic sulphide; and Gutzeit's tests. The various tests were described in detail, and the speaker concluded by saying that instances could be multiplied. He had only wished to raise the value of colorimetric analysis in their eyes and induce them to seek its help when estimating small quantities of substances with accuracy.

The chairman, and Messrs. Hargest, Rodgers, and Hord, contributed to the short discussion which followed, all bearing out a great deal claimed by Mr. Turner for colorimetric analysis.

LABORATORY CHEMICALS OF DOMESTIC ORIGIN.

By DR. M. O. FORSTER, F.R.S.

AT the annual general meeting of the Society of Chemical Industry, last July, attention was drawn to the pressing need of a British organisation fulfilling the functions of Kahlbaum, Schuchardt, Merck, and Schimmel (*Journal Soc. Chem. Ind.*, 263 T.).

Owing to the backward state of the organic chemical industry in this country prior to the war, no serious domestic attempt had ever been made to provide raw materials for the researches pursued by college and university staffs. Several factors contributed to this condition of affairs. From the purely commercial aspect the enterprise was unattractive, because it involves the skilled manipulation of a very large number of quite small quantities. In many cases the materials are seldom demanded, and such preparations represent locked-up capital, with an added risk of deterioration. In the next place, obliging Germans were ready to deliver 5,000 items at reasonable prices within a fortnight of receiving an order; moreover, they were willing to quote special rates for large quantities and to furnish also rare materials which did not appear in their lists. Any well-founded complaint as to the quality of a particular substance was met by a prompt supply of the purified article, and all these facilities were occasionally decorated with most entertaining letters in Anglo-German, expressing condolence, astonishment, and roseate promises of better behaviour in the future. The days when one infuriated dealer addressed a complainant embryo professor as "*Sie junger Mann*" instead of "*Sehr geehrter Herr*" were long since past. Altogether, it was very pleasant and amusing to order laboratory chemicals from Germany.

It has always been doubtful whether the industry was a profitable one, even in that country, where a large internal demand was assured; but cheap bottles and inexpensive *preparateurs* contributed to making both ends meet. Nevertheless, it richly deserved to be profitable, there being no question as to the great value of the service which it rendered. To research workers themselves it is unnecessary to emphasise this, because they are fully conscious of it, but it may be worth while to offer an explanation to others.

Even the best-equipped laboratories contain a very limited range of chemicals which are not in common use. Organic research has undergone such enormous development during the past forty years that the beginning of a fresh inquiry involves not only a bright idea but at least a few grammes of a material which is generally uncommon. It is admitted by active investigators that infant mortality of ideas attains a high percentage, ranging around 95. The labour of making one hundred relatively obscure compounds on the chance of five being useful is clearly wasteful if it is carried out by the man who can perhaps apply the five to developing the germ of a new general reaction or even of a new industry. As conducted at colleges, research work is pursued largely by men whose energies are, or should be, devoted primarily to instruction; but these are the very men whom it is most profitable to encourage in practising research, because they are reviewing their subject afresh each year in the light of new knowledge, and are responsible for infusing each oncoming generation of students with enthusiasm for chemistry. Hence the time-and-idea-saving function of laboratory chemicals in ample range.

A concerted effort to establish this industry in Great Britain is now required. Praiseworthy attempts to meet the need are being made by several manufacturers, and these should be encouraged, co-ordinated, and amplified; the field is too vast for individual cultivation, it requires too much detailed organisation. It should not be impossible, however, to consolidate these individual efforts in an organisation which would proceed somewhat as follows:

Taking Kahlbaum's pre-war list of 5,000 separate items as a basis, the first step would be to make a census of those compounds which are being produced already by various firms, with which, as affiliated members of the organisation, arrangements would be made for continued production of these and other materials for which they seem best fitted by their particular resources. Such a census would reveal the deficit as dividing itself roughly into two classes, (a) materials obtainable from the dye-makers and elsewhere in bulk, but in a commercial form requiring purification before distribution, and (b) materials not made in this country. Members of class (a) would be purchasable from the factories in question, and would frequently constitute the starting-materials for (b), which would require to be allocated among the constituent firms of the organisation; only in this way can overlapping be minimised.

For their own benefit the organisation would either establish a central distributing agency or would issue a comprehensive list covering their united products and indicating the firm to which purchasers should apply. At present the consumers have no means of knowing, without elaborate inquiry, whether certain materials are being made in this country, and if so, whence they are obtainable. This is because, although a limited number of old-established firms are making a gallant attempt to meet the situation, there exist also several small-range producers whose activities do not allow of adequate advertisement. All these should be correlated.

Meanwhile, the consumer must exercise patience. Howling for importation of German products, whether free or by licence, may well be postponed for at least one year in order to give time for the organisation of existing facilities to take effect. Such postponement will not seriously retard the prosecution of research in this country, because (a) the college staffs are fully occupied with the business which comes first to their hands—namely, teaching,—and (b) there are plenty of problems arising from war-researches which await solution. Moreover, in view of the success with which the colleges and universities produced synthetic drugs in the opening years of the war, it should be feasible to utilise their resources in the early stages of this particular enterprise. Excellent training for the more advanced students in working out the details of more difficult preparations would thus be offered.

It is not pretended that co-ordination of existing efforts and their amplification will be a simple matter, but winning the war was not a simple matter. The real danger lies in the fact that the vital importance of this industry, having been overlooked in the past, is now threatened with eclipse by the perplexing variety of post-war problems with which the chemical manufacturers are confronted. Such manufacturers are aware, however, that it is only by the cultivation of new ideas that

industry expands, either through economising production, finding unforeseen applications of natural resources, or utilising the by-products of existing operations, and they may be assured that new ideas will grow and multiply when fertilised by an ample range of laboratory chemicals.

CORNISH TIN-MINING INDUSTRY.

THE committee appointed by the Board of Trade to consider the question of non-ferrous mining in the United Kingdom met on October 28, 29, and 30, under the chairmanship of Mr. H. B. Betterton, M.P.

Mr. J. Faull, manager of the Tresavean Mine, near Lanner, in Cornwall, gave evidence to the effect that his company had spent large sums of money in unwatering a mine which has been a big producer of copper-ore in the past, and in developing a promising tin-ore shoot in the lower levels. They had been prevented from reaching the profit-earning stage by the intervention of the war. He outlined a scheme for further development, and suggested that the Government should assist on the principle of making advances for specific and agreed development to the extent of one-half of the estimated expenditure.

Mr. J. Nile, manager of the Grenville Mines, Cornwall, stated that serious losses had been incurred during the war, and that unless financial assistance was forthcoming to enable the mine to centralise the dressing-plant and to improve the system of pumping it would be impossible to continue operations. The mine made considerable profits in the years 1911-1913, but during the last three years had worked at a heavy loss. They had been further handicapped by a series of accidents at the time when men were returning from the Army, resulting in serious flooding of part of the mine. The company had in view a large scheme of development which, in Mr. Nile's opinion, held out good prospects of success.

Mr. H. E. Fern, the receiver and manager of Wheal Kitty, in the St. Agnes district of Cornwall, expressed the opinion that this district is exceedingly rich in mineral contents, and that an amalgamation of the mines in the district, if financial assistance was forthcoming, would result in re-establishing the industry and would result in considerable diminution of working costs. He thought the industry in many cases had suffered in the past from bad management and unsound financial methods. He thought the tin-ticketing system had worked to the disadvantage of the Cornish tin-mining industry, and welcomed the signs that a change in the methods of selling tin-ore was being introduced. Although he agreed with a suggestion that the nationalisation of royalties would probably do away with many of the difficulties due to the multiplicity of owners with which they now had to contend, he was not in favour of the nationalisation of the mining industry as a whole, as he did not think it would be administered by the Government as well as by individuals. He thought that representations should be made to the Commission recently set up for special consideration in the matter of railway rates, as is suggested in the case of the agricultural interest. He strongly advocated the establishment of a Department of Mines, with which copies of all mining plans should be deposited, the plans being at all times available for inspection.

Mr. T. E. Bennett gave evidence on the working and prospects of Kit Hill and Hingston Down Mines of the Duchy of Cornwall.

QUALITY OF AMERICAN DYES.

IN a report issued to the stockholders of the American Chemical Foundation, quoted in the *Board of Trade Journal*, a claim is made in favour of the superior quality of American dyes. The total American output of dyes in 1917 is valued in the report at 57,796,228 dollars, and that of 1918 at 83,095,404 dollars. During 1918 the export trade grew rapidly, the total exports of dyes for the fiscal year amounting to 16,921,388 dollars. In June, 1919, aniline dyes valued at 743,476 dollars were cleared for export from the port of New York.

The present strong American demand for Swiss dyes is accounted for in the report by the fact that most of the vat dyes are not manufactured in America in any quantity, but it is stated that the six months' supply of German dyes, permitted by the Government to come forward under the supervision of the War Trade Board is expected to remedy some of the defects in the vat dye situation. Meanwhile, three different plants are manufacturing indigo in quantities, and are promising other vat dyes in the near future. In regard to the control of dye factories in the occupied areas in Germany, a resolution was adopted by the dye section of the American Chemical Society that an urgent request should be made to the President that America should have her share in the operating control of these factories, and that qualified representatives should be stationed there, the information gained to be used for the benefit of the American industry.

It was also resolved that as the manufacture of dye from coal-tar distillates involves the same process and material as that used in the manufacture of explosives and poison gas for military purposes, the question of the importation of dyes and bases of intermediates be made a military question, on the ground that importation is a menace to the possible future defence of the country, as it fosters foreign industries which would furnish an enemy with munitions of war, and discourages the development of home industry essential to defence.

Among other resolutions passed was one endorsing pending legislation to establish an independent Patent and Trade-mark Office, and a United States Court of Patent Appeals at Washington, and one protesting against the printing on hotel laundry bills of announcements to the effect that no responsibility would be assumed in caring for guests' laundry, owing to dyes.

A prominent American manufacturer does not agree with some of the claims advanced in the above report. He asserts that the public demands fast dyes, and manufacturers will soon be tired of employing dyes which will not give satisfaction.

NEW ISSUES. -An issue of 4,000,000 7 per cent cumulative Preference shares of £1. each at par is announced by Messrs. Lever Brothers, Ltd., Port Sunlight. The present issue is made to provide for the portion of the cash consideration shortly payable in respect of the purchase of the ordinary shares of the soap businesses of Joseph Crosfield and Sons, Ltd., and William Gossage and Sons, Ltd., from Brunner, Mond and Co., and also to provide further working capital required in connection with the development and extension of the company's business generally. The subscription list will be closed on or before Monday next. -An issue of 1,500,000 £1 shares of the Scottish-American Oil and Transport Co. at par was offered on Monday for public subscription. The company has been formed particularly for the purpose of acquiring common stock of the Southern Oil and Transport Corporation, of Delaware, U.S.A.

THE CHEMICAL INDUSTRY CLUB.

FIRST ANNUAL DINNER.

THE first annual dinner of the Chemical Industry Club was held at the Tallow Chandlers' Hall, London, on Friday of last week. Prof. W. B. Hodgkinson, C.B.E., presided, and among those present were Sir William Pope, K.B.E., Mr. H. B. Ferguson (technical adviser to the Military Governor, Cologne), Mr. John Gray (president of the Society of Chemical Industry), Mr. Samuel Rideal (president of the Society of Public Analysts), Mr. Julian Baker (chairman of the London Section of the Society of Chemical Industry), Mr. R. B. Pilcher (registrar of the Institute of Chemistry), Mr. F. Cooper (Master, Worshipful Company of Tallow Chandlers), Mr. E. H. Coley (hon. sec.), Capt. C. J. Goodwin (hon. treasurer), Dr. Robert Mond, and Mr. A. Chaston Chapman. The company numbered nearly 100.

Following the toast of "The King,"

Mr. H. B. Ferguson proposed the "British Chemical Industry." He said he felt it an honour to be asked to come from Cologne to propose so important a toast, and it was a presumption on his part to address so representative an assembly as was present. Nevertheless, possibly what he had to say might in some slight measure accelerate the industry in attaining its ultimate destination, that of surpassing the chemical industry of any other country.

NATIONAL IMPORTANCE OF THE CHEMICAL INDUSTRY.

When one reviewed the great strides and astounding progress that the application of chemical science to industry had played during the past generation, said Mr. Ferguson, one was forced to the conclusion that if the same progress was made in the future it would not be far distant before the nation which possessed the greatest chemical industry would be commercially the most prosperous and possess the weapon to ward off a repetition of such struggles as we had been through in the past five years.

While possibly an appreciative address bestowing praise on the great strides our chemical industry had made during the past five years might be more pleasant to listen to, it was only by the frank acknowledgment of our faults and the study of our shortcomings that progress was made, and, therefore, having had the opportunity of living for the past nine months in the land which to-day possessed the greatest chemical industry in the world, and having, further, been through a great many of their factories, and studied their methods and their organisation, he felt it would be of greater advantage if he dwelt upon those particular phases of the chemical industry in which our great German competitor excelled us, than on those branches in which we surpassed the Germans.

Whilst it was admitted that the British scientist was second to none in reasoning powers and inventive ability, nevertheless we had been too content in the past to lay the foundation-stones of almost every branch of science, and had not always followed up our discoveries and accrued the most benefit from them. Particularly was this so in the chemical industry, in which, until recent years, we had primarily confined ourselves to the manufacture of heavy chemicals.

Some 20 or 25 years ago the Germans, realising that in those days, not having the shipping and trading connections that we had, they were in no position to compete

with us in the manufacture of heavy chemicals, shrewdly turned their attention to converting their heavy chemicals into pharmaceutical products, fine chemicals, organic dyes, etc., realising that the railway and shipping charges on these commodities bore relatively a smaller percentage to the total cost than was the case with heavy chemicals. The men who founded the greatest chemical combine in the world, the Interessens Gemeinschaft, were men of great courage and scientists of extraordinary vision. They sunk all internal jealousies in the one great effort of making their chemical industry as a whole as perfect as possible. Some of their methods unquestionably were not very creditable. They pursued a policy of forcing to the wall foreign competitors by underselling them, never by buying them, and later re-imbursed themselves for what they had been out of pocket by putting up the price. They obtained all the advantages of the American system of amalgamation and trusts without the disadvantage of destroying individual competition among their members, for each factory maintained a separate identity and its own board of directors, although coming under the combine. They further supported a world system of commercial intelligence, which is one of the most elaborate organisations of its kind.

NECESSITY FOR ORGANISATION.

If we were going to compete successfully with this great octopus on the other side of the Channel, it was incumbent upon us to start, in order to protect ourselves, some such organisation. There was already in embryo such an organisation, the Association of British Chemical Manufacturers, to deal with internal matters at home, but they must support the organisation to the same extent as the German chemical manufacturers had supported theirs. They could not be suffering from individual jealousies and imagine that they were going to win the prize. Therefore, the Association of British Chemical Manufacturers was using at the present time the skeleton system of world commercial intelligence which had been laid down by the Federation of British Industries, and inasmuch as the great metal and textile industries were supporting the Federation, the cost that would fall upon the chemical industry for foreign intelligence of a commercial nature would be reduced to a minimum.

The Germans had taken the same pride in their chemical industry that we in the past had bestowed on our Navy, and the German capitalist and the German banks had supported their chemists in the construction of some of the boldest-planned work that man had created, even with very little hope of an immediate return, realising that capital which backed the application of science to industry would, in the long run, obtain a return for its investment. As a result of Germany's support of her chemical industry, she had taken an increment of profit off the great textile industries of this country, and, in fact, the textile industries of the world, through her monopoly of organic dyes, and who could say the time was not far distant when she would not place a similar tax on the very food we grow in our Empire through the sale of cheap nitrates as fertilisers.

In the past five years we had launched out into almost every branch of chemistry, and we were beginning to realise in a hazy way the great importance of the chemical talent which we have in this country and which we had not been making use of. It was an anomaly that we, with all our talent, should have allowed the Germans to have outstripped us in many branches of the chemical industry, and it was natural to seek a reason for this.

The reason was the want of appreciation of the latent capabilities of the young chemist as he left the university. These young men were confined, as a rule, in some chemical laboratory in one of our factories, where for the rest of their existence they spent their time messing with test tubes and chemical reagents with no wider horizon than the four walls of their laboratory to look to, and no hope of a just return for their talents and their labour, while the works and the plant were being operated too often by men with little or no technical training.

NEED FOR THE TRAINED CHEMIST.

Some seemed to think in a hazy way that it was Germany's wonderful system of organisation which was responsible for her progress in the chemical industry. We were just as good organisers in this country as the Germans, and he could assure them that in the metal and many other industries to which we had applied ourselves, it would be found that in mass production, motion study, and many other methods of cheap production, mostly emanating from America, we were not one whit behind Germany, but our failure in the chemical industry had been due to the attempt to organise it with men who were not chemists. Having controlled some hundreds of chemists in one of the largest national factories, he wished to say a word, for the benefit of the chemists who were present, on administration.

The young chemist coming out of the university was in no position to control anything, and the longer he stayed in the university the more fixed his ideas became and the more difficult it was to train him. When he first came on the works he would be put into the laboratory until such time as he had learned methods of sampling and analysing the particular products dealt with in the factory. He then might be put in liaison between the laboratory and the factory, and later he went on as control chemist on the plant. Some men were naturally not gifted with the personality for controlling labour and administering their work. These would have to remain on research work or the study of plant yields and efficiencies, but he could assure them that the average chemist in this country was capable of being a very good administrator if he was given only the opportunity and the chance. The first thing he must do was to write a complete description of his plant and then a complete description of the method of operating it, and his most important studies of all at first should be along the lines of controlling labour. The confidence of labour was the first thing that the man who attempted to control labour must obtain, and it could be better obtained in the off-duty time than under the strict discipline existing during factory hours.

It was only by the industry combining together in the manner he had outlined that they could face the future competition of the other great nations without fear.

Mr. John Gray (president of the Society of Chemical Industry), who replied to the toast, endorsed what Mr. Ferguson had said as to the necessity for pulling together in the industry. They had only one master—viz., the public,—and the industry or the trade which could serve the public best and cheapest was the industry which was going to make headway and progress. There was undoubtedly a great deal of latent talent in the industry, but if the industry was to progress at all it must attract to it the very best brains in the country. It was quite true that in the past the young chemist had not been adequately remunerated, and not only that, but he did not receive the encouragement to advance in his pro-

fession that he ought to have received. There was too much standing aloof by the men who had made a certain position. These young men should be taken by the hand and helped forward, and he could conceive of nothing better to achieve this than by clubs such as the Chemical Industry Club.

With regard to training young men in administration, he favoured the policy of every promising young man being taken into the deliberations of the senior administration, not necessarily for the purpose of taking part in them, but for the purpose of learning what was involved in the higher management work of the concern. He knew that was being done in some cases with great success. They must all agree that the days of exclusiveness were over and that they must get closer together with the members of the staff and encourage them in every possible way.

THE NATIONAL CHEMICAL FEDERATION.

Sir William Pope, proposing "The Chemical Industry Club," said the British Empire was entering upon a period of technical and industrial prosperity which had never been equalled before. At present they were more or less taking stock of the situation to see what they were going to do in the future. As chemists they should see first that their profession took its proper place in national affairs, and secondly, that they got a proper remuneration for their efforts. First of all they might inaugurate a body which would bring together all the great societies interested in chemical affairs. Such an organisation was, in fact, in being, and was gradually and slowly and very painfully emerging. The National Chemical Federation was in existence, and consisted of representatives of the 15 or so societies which were intimately concerned with chemical matters. That, however, was starting the business at one end. To start at the other end they needed some sort of social organisation which would bring all chemists together, men of different types and different modes of thought, and cause them to meet together in a friendly kind of way for informal conversations and exchange of opinion. He confessed that when he heard a year or so ago that the Chemical Industry Club was projected, he was not very sanguine as to its success, and he was very happy to be able to confess that he judged his fellow-chemists wrongly, and to congratulate the founders of the club upon the ability they showed in reading the signs of the times, and the skill with which they had already constructed a large and powerful club.

Mr. H. E. Coley, hon. secretary to the club, responded. They had among their members men whose names were laboratory names, and they had manufacturers, but they had not all the manufacturers, nor all the leading chemists. Those who had reached the top of the pinnacle did not, perhaps, need such a club as this. It was a club proper, not a hole-and-corner club, and the leaders of the profession and the leaders of the trade should support it because it gave an opportunity for the young men, whom they were likely to employ, to broaden their minds in such a way that they were of greater value when they got them into their employ than they would otherwise have been.

The toast of "The Worshipful Company of Tallow-Chandlers" was proposed by Mr. H. M. Ridge, and responded to by the Master of the company, Mr. F. Cooper.

The final toast, that of "The Guests," was proposed by Mr. Bernard F. Davis, and responded to by Dr. S. Rideal and Mr. Julian Baker.

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

THE first meeting of the session was held in the rooms of the Chemical Society, Burlington House, on Monday, Mr. Julian Baker, chairman of the Section, presiding. It was announced that Dr. Charles Keane, the retiring chairman, had been elected a vice-president. On the motion of the chairman, seconded by Dr. M. O. Forster, the sincere thanks of the London Section were accorded to Dr. Keane and Dr. Stephen Miall for the admirable manner in which the arrangements for the annual general meeting in July were carried out.

BLACK-LEAD PENCILS AND THEIR PIGMENTS IN WRITING.

In a paper on this subject Mr. C. H. Mitchell dealt first with the history of pencils, and showed how difficult it has been to improve upon the quality of the Borrowdaile (Cumberland) graphite, which was first discovered in 1560, and was used from that time onwards until the latter half of the 18th century for all the black used throughout Europe. The graphite was simply sawn into thin veneers with a wedge-shaped edge, the veneers being glued into a square groove in the wooden holder, the upper segment of wood then being glued on top. About 1840, the Borrowdaile mine, which was only at first worked for a few months in the year, but later more continuously, showed signs of exhaustion, and various methods of using the graphite dust in the works were tried. The most successful of these was Brockenden's process, in which the finely sifted graphite was subjected to a pressure of 5,000 tons [this figure was challenged in the discussion] per square inch, while air was simultaneously exhausted from the press. This yielded compact blocks of graphite which could be sawn up in the same way as the natural graphite. In 1761 Faber's works were established in Nuremberg, and mixtures of powdered graphite, with sulphur, resins, gums, and other ingredients, were used for pencil pigments, but the modern process of pencil manufacture originated with Conté, of Paris, in 1795. This consisted of mixing finely elutriated clay and graphite into a paste, which was forced through small openings in a cylinder in order to produce circular threads of pigment. These were dried, heated in a covered crucible, and glued into the grooves of the wooden holders. The hardness of the pencil depended on the proportion of clay and the degree of baking. This process was introduced into England early in the 19th century, and overlapped the older one, which continued to be the principal process. A further development was the incorporation of wax with the pigment. Various other additions, such as lamp black, sulphur, and resin, have from time to time been incorporated with the graphite composition, and the pigment in some of the cheaper grades of pencil consisted largely of lamp black.

The author gave results of analyses of a large number of pencils, obtained for the most part from the Geological Museum, but also from Messrs. Acheson and Mr. Birkbeck, the former proprietor of the Greta Pencil Works at Keswick. The various specimens investigated showed the following proportions of carbon:—Borrowdaile graphite, 90.33 per cent.; another sample showed 90.73 per cent.; Ceylon graphite, 92.78 per cent.; Swedish graphite, 43.84 per cent.; Swedish graphite, 79.63 per cent.; Canadian graphite, 93.21 per cent.; Siberian graphite, 77.45 per cent.; Acheson's graphite, for pencils, 99.83 per cent.; and Acheson's graphite, for electrodes, 96.8 per cent. In judging the suitability of a graphite

for pencil-making, the chemical points to which attention should be directed were: (1) The proportion of carbon; (2) the amount of silicates; and (3) the iron. The physical nature of the graphite was also important, and the author pointed out that it was possible to say, by a microscopical examination of the marks made by graphite on paper, why certain specimens of graphite, relatively poor in carbon, gave better results than specimens of more crystalline graphite containing more carbon. The paper also described methods of analysis of pencil pigments.

Prof. J. W. Hinchley said that the manufacture of pencils was a secret industry, and it was obvious from the paper that the author had no inside knowledge of the present practical conditions. He thought more reference might have been made to the English workers, and he believed there was still in Wolff's works here the original press for compressing graphite dust. The pressure, however, was 200 tons, and not 5,000 tons as the author had said. The material could not stand the stress which would be set up with that pressure. A most common wax used at one time was spermacetti, but its high price now prevented its common use. The modern manufacture of lead pencil was far away from the Conté process, and the similar process which Hardmuth claimed to have invented three years later. He did not know any maker that produced a pencil which could compare with the old Borrowdaile graphite, untouched as it was except by nature.

Dr. W. R. Ormandy said that scratches produced by pencils were due to the silica in the clay, and although it was possible to get rid of the greater portion of the siliceous matter by washing and using 97 tons of water to 3 tons of clay, there was still a very large amount of siliceous matter present. He had found in one of the clay pits in East Prussia a clay which was of such a low quality that it was only used for making drain pipes, but by an electrical method they were able to separate the clay from the other matter, and, whereas it was originally sold for 6s. per ton, the pencil manufacturers of Germany had paid £30. per ton for it during the war. Moreover, the dispersed clayey substance had the power of absorbing dyes to a degree which was absolutely unequalled by any of the ordinary or natural clays.

Prof. Hinchley said that artificial graphite was almost impossible as a pencil-making material. The question of cost put it out of court altogether. It might be used, but there was no money in it.

Mr. Mitchell, replying to the discussion, confessed blank ignorance of the present methods of pencil manufacture. The figure of 5,000 tons pressure had been questioned by himself also, but he found it referred to in print on two occasions.

SHAWINIGAN CHEMICAL INDUSTRIES.

In this paper, Capt. E. T. Sterne gave a most interesting account, illustrated with coloured lantern slides, of the development of the water-power at Shawinigan Falls, in Canada, in general, and the chemical industries which have arisen there in particular. There are now installed 320,000 H.P., with extensions of an additional 650,000 H.P., which will become available as the district develops. The total possible water-power, however, is capable eventually of giving 1,000,000 H.P.

One of the earliest chemical industries is the manufacture of aluminium upon the well-known Hall process by the Northern Aluminium Company. The Belge-Canadian Pulp and Paper Company is the second largest chemical industry to be located at Shawinigan, and the

works are now producing 165 tons of ground wood-pulp, 90 tons of chemical pulp, and 90 tons of paper per day. Carbide manufacture has been carried on by the Canada Carbide Company since 1903, the capacity of the works being 200 tons of carbide per day, the power demanded being 40,000 H.P. The Shawinigan Electro-Metal Company came into existence in 1915, owing to the shortage of magnesium metal, and during the last three years of the war supplied magnesium in both stick and powder form to the extent of about 600 lb. per day. One of the latest additions is the Canadian Aloxite Company, which is manufacturing abrasives of various kinds as a subsidiary of the Carborundum Company of America. The Canadian Ferro-Alloys Company has recently completed a plant for the manufacture of ferro-silicon and other ferro-alloys, and utilises 6,000 H.P. There are also the Prest-o-lite Company, which manufactures compressed acetylene gas, and the Canadian Electrode Company, which deals in carbon electrodes for electric furnace purposes.

Possibly the most interesting chemical development at Shawinigan, however, and one of the most notable achievements in the chemical world during the war, has been the development of the process for the manufacture of acetic acid and acetone from calcium carbide. This was directly the result of the British authorities approaching the Shawinigan Water and Power Company. Work was started in December, 1915, and intensive research was carried on by five Canadian chemists, with the result that construction work was started in May, 1916, and in January, 1917, the first carload of acetone was shipped across the Atlantic. The process divides itself into the following five stages, each of which was described in detail in the paper:—(1) Production of acetylene from calcium carbide; (2) production of mercuric oxide from metallic mercury; (3) production of acetaldehyde from acetylene; (4) oxidation of acetaldehyde to acetic acid; (5) conversion of acetic acid into acetone. The average efficiency over a period of some months was about 85 per cent. In March, 1918, a duplicate plant was started for the American Government, and was completed when the armistice was signed. The combined output would have been 1,600 tons of acetic acid per month, and the company intends to work both plants now commercially.

The Chairman, in proposing a vote of thanks to the author for his paper, which, he said, was hardly one which lent itself to discussion, said that the fermentation process, as carried out in this country, was substantially regarded as a failure.

CLIP FOR RUBBER CONNECTIONS.

There was exhibited at the meeting a clip for preventing rubber connections from slipping off glass and metal tubing, and for attaching pressure-taps to pumps, designed by Dr. Charles A. Keane and Mr. G. Patchin. This takes the form of a hinged brass grip about an inch long, which is placed over the rubber tubing, the two halves being fastened together by means of a screw with a milled head. Its effectiveness in practice was demonstrated by its application to various apparatus.

NEWCASTLE SECTION.

THE members of the Newcastle Section of the Society of Chemical Industry on Thursday night (October 30) paid a visit to the iron and steel works of Messrs. Palmers, at Jarrow on Tyne. The visit, which was the first of a series arranged for the winter session, was of great interest to the fifty members who took part in it. Mr. Hewitson Hall, general manager of the iron and steel

works, was in charge of the party, and he was assisted by the following officials: Mr. G. W. Hewson, works' chemist; Mr. T. H. Pearson, engineer; Mr. J. H. Riddale, blast-furnace manager; Mr. J. Knowles, electrician; and Messrs. Hargest and Rogers of the works' laboratory.

The first part of the works visited proved especially interesting to chemists, being the gas-engine house and the gas-cleaning shed. The four massive gas-engines, used for blowing and providing electric power, are driven entirely by the waste gas from the furnaces, which, as Mr. Hall explained, had formerly just been sent into the atmosphere. The cleaning process, consisting of a special "shaking" plant which collects the flue-dust from the gases, was carefully inspected. The amount of potash eventually recovered from the dust is very considerable and of great value. From the cleaning shed the party went to the blast-furnaces, where tapping was in progress. The "tap," in this instance, was conveyed in a 40-ton ladle direct to a mixer in the steelworks. At the steelworks the mechanical charger was an object of interest, and a large basic furnace in process of construction provided an admirable opportunity for examining the structure of a steel furnace. A visit to the cogging and bar mills and the engine works concluded the tour.

Later the party was entertained to supper by the company, and Mr. Hall presided over the gathering.

Dr. J. H. Paterson moved a hearty vote of thanks to Mr. Hall and his assistants, which was seconded by Mr. W. Jones and carried with acclamation.

In responding, Mr. Hall said of late years it had become increasingly evident to enlightened minds that the progress of industry, and progress even outside industry, lay largely in the field of chemical research. The iron and steel industries had been forced by circumstances to probe deeply into the chemical aspect of every matter which was to undergo reorganisation. Prior to the war it was easy to get people to invest money in any wild-cat scheme in Patagonia, but it was difficult to get people to spend money in making scientific researches in industry at home. He was glad to say, however, that their efforts in that direction had met with success, and the object they set out with—to save fuel and labour costs—had been more successful than they anticipated. He referred to the tremendous success of the utilisation of waste gas from the furnaces. Before the war Germany had led the way in the utilisation of waste power, and he thought it was a tragedy that we had been so late in starting on the same lines, especially when they remembered that the war had proved that the brains were in this country all the time. They had a long way to go yet, and during the next five years the economical development of the production of iron and steel would have to be pressed forward to meet the competition of America in the markets of the world.

GIFTS FOR SCIENTIFIC RESEARCH.—At a general meeting of the members of the Royal Institution on Tuesday, Sir James Crichton-Browne, treasurer and vice-president, in the chair, the special thanks of the members were returned to Mr. Richard Pearce for his donation of £100 to the fund for the promotion of experimental research at low temperatures; to Mr. Robert Mond for his gift of laboratory material; and to Sir Humphry Davy Rellston for his gift of a drawing of Sir Humphry Davy's birthplace and a water-colour of his statue in the Market Place, Penzance. Lord Rayleigh, Mr. E. Griffin, Lieutenant-Colonel A. E. le Rossignol, and Mr. E. Basil Wedmore were elected members. The chairman announced the death of Professor A. P. N. Franchimont, an honorary member.

IMPORT RESTRICTIONS ON DYES.

A SPECIAL correspondent of the *Morning Post* has written the following interesting article, in which the facts concerning the restrictions on the importation of German dyes into this country, and the position of British dye consumers, are discussed:—

Considerable misapprehension would appear to exist in regard to the importation of German dyestuffs into this country. It has been said that delay in the ratification of the Peace Treaty is having a serious effect on the wool textile industry in Yorkshire, owing to the inability of the Board of Trade to grant licences for the importation of German dyewares until conditions of the Treaty become operative. This is not the case.

The position is that under annexe 6 to the Reparation Clause of the Peace Treaty the Allies have the right, through the Reparation Commission, to call upon Germany to deliver 50 per cent of the stocks of dyestuffs existing in that country or under German control on the day of the coming into force of the Peace Treaty. While legally it is not possible to anticipate this, the British Government, in their desire to assist those industries which consume dyestuffs, have made arrangements for an interim supply, which will shortly be available in this country. The Board of Trade, in a letter to the Bradford Chamber of Commerce, dated October 22, state:

"The Board fully appreciates the necessity for securing a supply of such essential dyestuffs as are unobtainable in sufficient quantities from British sources of manufacture, and with this object in view are making arrangements, which it is hoped will be completed in the near future, for securing an interim supply of such dyestuffs from Germany under the terms of the Peace Treaty. An announcement as to these dyestuffs and the manner in which they will be available for consumers will shortly be made."

GERMANY CRIPPLED.

These imported dyestuffs, it has to be kept in mind, will consist only of products not obtainable or not procurable in sufficient quantities in this country. They will come in under licences granted by the Licensing Committee of the Board of Trade. The policy of this Licensing Committee is to give the re-created British dyeware industry an opportunity of establishing itself—not exclusively for the benefit of the industry, but for the protection of consumers. Therefore, while there is no wish to prevent consumers from getting the materials which they really need, there will be no such thing as indiscriminate imports. This action is being taken in the interest of the consumer, who no longer desires to be under the menace of the German monopoly. What this German monopoly meant in the past and the manner in which it was wielded was strikingly illustrated by Dr. Lisa Haneberg in the *Berliner Tageblatt*. Analysing the powers of the Reparation Commission in regard to dyewares, he remarked:

"Assuming that the German output of dyes were composed in the following proportions: (1) 30 per cent. of azo and triphenyl-methane dyes, (2) 20 per cent. of indigo, (3) 20 per cent. of sulphur dyes, and that of the remainder 20 per cent. were the extremely difficult vat dyes, such as thioindigo and anthraquinone dyes, the Commission has it in its power to deplete Germany altogether of certain dyes, and thereby to cut her off from the world market, while at the same time creating a monopoly for itself. Of the groups named, for instance, the first three are more easy to manufacture.

The Commission will, therefore, not require their surrender, as the enemy countries are themselves able to produce them. On the other hand, it will demand delivery of anthraquinone and thioindigo dyes, which the Entente countries have, in spite of all efforts, not been able to produce, and which they need to complete their range of colours. This, however, will deprive the German industry of the possibility of concluding the so-called 'combined contracts'—i.e., German factories will no longer be able to bring pressure to bear on their customers to buy azo dyes from them rather than from other manufacturers, by means of a declaration that the difficult German vat dyes will only be sold on condition that a certain amount of the other types are taken with them."

SAFEGUARDING BRITISH INDUSTRY.

The question may naturally be asked: "What about the assertion that after the war Great Britain would be independent of supplies from Germany?" So she will—in time. In spite of all the difficulties of the period of the war, the British dyestuffs industry made very great progress, but time must be allowed those who are handling the question to make good. The Germans had been at work steadily for nearly thirty-five years, for the greater part of which period the British industry was stagnant. It is a terribly complicated and scientific question, which must be solved in the interest of the consumers. During the period of solution no one wants to deny them the supplies they need, but these must be controlled, and the Germans must not be allowed to come freely into our market. To avoid misconception it may be well to refute the assertion that the wool textile trade of this country is suffering from lack of German dyestuffs. This is part of an insidious campaign, said to have been inaugurated by pre-war agents for German dyes in this country, who are in danger of losing much business through the import restrictions. The wool trade in this country just now is full up with work, and its members are in a better position to-day, from the point of view of raw materials and dyestuffs, than their competitors in any part of the world.

AMERICAN PROTECTIVE MEASURES.

In regard to fostering the dyestuff industry, the Americans are taking the same viewpoint as the Government of this country, but their measures, through the tariff, are much more drastic. So keen are the United States about safeguarding the industry in the interests of national defence that in the Longworth Bill, now before Congress, it is proposed to raise the duty on finished dyestuffs from 30 per cent. *ad valorem* and 5 cents a lb. surtax to 45 per cent. *ad valorem* and 7 cents per lb. surtax, and the tax on intermediate products from 15 per cent. *ad valorem* and 2½ cents per lb. surtax to 40 per cent. and 6 cents respectively. At the same time it is proposed to introduce a licensing system whereby no synthetic dyes or coal-tar derivatives of any sort can be imported into the United States of America without a definite licence. The text of the Longworth Bill contains the following passage: "The Commission shall issue no licence which, alone or with other outstanding licences, shall permit the import of a quantity sufficient to discourage, postpone, or endanger the domestic manufacture of such products."

BRUNNER-MOND DEVELOPMENT.—It is stated that Messrs. Brunner, Mond and Co., Ltd., have purchased land at Stafford for the erection of works to be devoted to their ammonia-soda process.

A NEW SILICIOUS FILLING MATERIAL.

AMONG the results of the war that can be described as beneficial must be placed the fuller realisation of the value of "waste" products. The need for replacing some article the supply of which was curtailed, if not entirely interrupted, by war conditions, led to more than one revolution in manufacturing processes, while the closure of markets often left no option but an endeavour to earn a profit by the utilisation of products formerly consigned to the dump as "waste."

Few industries have had to contend, even in normal times, with a greater hindrance in the shape of unusable residue than that of slate quarrying, where at least 70 per cent. of the rock won in the past was waste. The appearance of the waste heaps of such quarries as the famous Penrhyn and Dinorwic, in North Wales, renders sufficiently credible the statement that the commercial success of such a project as slate quarrying is to be measured by the area and accessibility of the land available for tipping purposes. It is safe to assume that the slate waste heaps of North Wales to-day cover many hundreds of acres of valuable land.

At last, however, a move has been made in the direction of turning the millions of tons of waste slate comprised in these unsightly masses into articles of commercial value, by the process of finally reducing the large fragments into powder form, and the opportunities for its use in industry will be manifest from the accompanying typical analysis:—

	Per cent.
Silica (SiO_2)	60.66
Alumina (Al_2O_3)	20.36
Ferric Oxide (Fe_2O_3)	8.26
Lime (CaO)	0.96
Magnesia (MgO)	2.10
Potash (K_2O)	1.41
Soda (Na_2O)	3.08
Carbonic anhydride and combined water..	3.17
	100.00

The North Wales Development Company, Ltd., which has acquired a fifty years' lease of the Pantdreiniog slate quarries at Bethesda, Carnarvonshire, has been carrying on varied and extensive experiments since the end of 1918, and is now marketing the powdered slate under the name of "Myrtox," exhaustive tests having shown its commercial value in many directions.

A full list of the trades and processes in which a silicious inert filler, which is essentially the description of the fine slate powder, can find an application is obviously not easy to give; but among others it has been demonstrated that it is useable in the following manufactures: Asphalt, bricks, cement, abrasive soaps, cleansers, glass, linoleum, moulded and mechanical rubber goods, pottery, slabs and tiles, distempers, paints, insulators, etc. It produces bricks which are at the same time dense, strong, and hard, and which should show a considerable saving in manufacturing cost. The silica content also ensures that they are capable of withstanding a very high temperature. Excellent samples of common glass bottles, pottery, and tiles made from the slate waste are on exhibition, and for green and amber glass it appears eminently suitable.

We are assured that firms who have already used the powdered slate waste as a filler in the manufacture of such rubber goods as cab tyres, boot soles, and cheap moulded goods, have expressed their entire appreciation of it, as it is entirely inert and has a good binding effect on the rubber. Asphalt is another substance where the slate waste in the form of an impalpable powder has definitely been proved of high value. It will be realised that the

wearing property of an asphalt surface depends largely upon the absence of voids in its composition and surface, so that the finer the filler which forms the admixture with the bitumen, the more likely is perfection to be attained. Much of the "Myrtox" yield is an air-floated dust which is collected by Sturtevant fan dust-collecting plant, in the form of a powder of the very finest nature.

For distempers, fire- and acid-proof paints, etc., the slate waste powder seems admirably adapted, and for many other purposes where an inert fine filler is indicated it should have many advantages over other substances now in use, in view of the fact that its source enables it to be put on the market at competitive prices, and that accurate grading of the powder from 20 up to 200 mesh and over is guaranteed.

FIXATION OF ATMOSPHERIC NITROGEN.

THE Secretary of the Ministry of Munitions announces that the report of the Nitrogen Products Committee of the Munitions Inventions Department will shortly be published.

This committee was appointed by the Minister of Munitions (Mr. Lloyd George) in June, 1916, and the report embodies the results of a full inquiry into the nitrogen problem, extending over two and a half years. Its recommendations include proposals for meeting at home a portion of the growing demand for various nitrogen products; also proposals for conserving and increasing the output of by-product ammonia from gas works, coke-ovens, etc.; for securing the better utilisation of the national resources in coal and for reducing the consumption of raw coal as fuel. The committee also indicate directions in which further research on the nitrogen problem initiated during the war should be continued for the general benefit of the country.

The main interest in the report lies in the direction of the future development in this country of the fixation of atmospheric nitrogen. In connection with this the Ministry of Munitions commenced during the war the erection of a factory at Billingham-on-Tees, covering 271 acres. At the conclusion of hostilities work on the construction of the factory as a war measure was suspended pending further consideration as to the best method of fulfilling the intentions of the scheme. There is now reason to judge that by a modification of the scheme it can be made capable of producing ammonia synthetically on a commercial scale, and the Government have decided that further development should be left to private enterprise.

The Minister of Munitions is accordingly prepared to consider offers for the acquisition of the partly constructed factory at Billingham, with plant and other realisable assets, from persons or firms in a position to develop successfully the fixation of atmospheric nitrogen. The adequate assurance of the production of nitric acid, etc., for service explosives, will be a condition of the transfer.

Those desirous of making offers should communicate direct with Sir Howard Frank, K.C.B., Ministry of Munitions, 4, Whitehall Court, S.W. 1.

NEWCASTLE CHEMICAL CLUB.—The members of Newcastle-on-Tyne Chemical Club held a most successful whist drive on Friday night (October 31) in their rooms at the Drawing Room Cafe, when Mr. H. Dunford Smith, secretary of the Newcastle Section of the Society of Chemical Industry, carried off the first prize.

AMERICAN CHAMBER OF COMMERCE IN LONDON.

DRUGS, CHEMICALS, AND DYESTUFFS COMMITTEE.

AT a recent meeting of the Committee on Drugs, Chemicals, and Dyestuffs of the American Chamber of Commerce in London, Mr. I. A. Keene presiding, discussion took place on several questions relating to the importation of chemicals and allied products.

IMPORTATION OF SALICYLATES.
